: > The new C startup would determine which convention is in use, if at all,
: > by the command line length byte, and if the new convention is in use
: > strip the first character.
:
: The MWC startup code doesn't use the length byte for validation. Thus,
: this convention will break existing MWC-compiled programs.
:

This method is of no interest anyway: there is NO compatibility !
it doesn't bring anything more than the space-adding scheme.

I think the best way is to add after ARGV= the places of NULL argument
IF ANY (adding dummy chars, where there should be a null string, if you
wish but not necessarily).
This wouldn't change operation when there are no null argument and would
permit to use binary data as before (but always limited to binary values
above 0)
If MWC compiled apps would crash is of course of no importance as it would
only occur in cases where there IS a null argument: it would anyway have
crashed (or misinterpreted the command line) !

3081. malloc problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-07 14:00:13 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Aug7.140013.4468@csi.uottawa.ca>
Source record: 43180

I've been trying to get a couple of (supposedly) generic POSIX programs running, and am getting the same complaints, relating to the use of the sundry {a,m,r}alloc functions.

To wit:

I try to compile programs that use malloc, and get TWO complaints (for each member of the family that gets referenced):

warning: alloca redefined <in something like "systems.h">

previous declaration of alloca in /dev/d/gnu/include/memory.h

There seem to be some macros coming in between things, so it's not 100% clear what is or should be happening.

I'm running GCC 2.2.1, with the MiNT libraries, patch level 20.

(Specific applications: I'm trying to compile gdbm for possible use with Perl. I don't have a PARTICULAR use for this, but would like at least to see it work, and wouldn't mind putting it in the archives... Also, a linear program solver was just posted on Comp.sources.reviewed. I do a lot of LP work.)

(By the way, I DID get G++ running. Got several messages with the correct answer - rename gcc-cc1+.ttp to gcc-cc1plus.ttp - and it does

3082. DMA sample playing

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-07 15:26:31 UTC
From: vicb@clark.edu
Message-ID: <1992Aug7.152631.7654@clark.edu>
Source record: 43179

Can anyone tell me where I can find a text file that explains
using the DMA for sample playback? Either that, or if it so simple that
it can be explained quickly, 'how is it done?'
I am using C.

Thanks in advance,
Victor Bruhn

3083. Re: Null arguments with ARGV

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-07 16:44:46 UTC
From: HUSFELD@usmv01.usm.uni-muenchen.de
Message-ID: <1992Aug7.164446.8583@news.lrz-muenchen.de>
Source record: 43181

Oops, it seems my newsreader doesn't understand me. Sorry for broadcasting this silly citation-only message yesterday, the problem should be fixed by now. Here is what I intended to send instead.

I have seen this quest for "What is MWC doing with its ARGV= value" several times now in this thread, so yesterday I sat down to re-read MWC's docs and disassemble some bits from the libc library. Here are my results so far. Note that this is not exhaustive but it should prove that the ARGV= value cannot be used for other purposes than those intended by Mark Williams without breaking existing MWC programs.

First of all, Mark Williams' documentation describes the ARGV= value as the `iovector'. It is a string of characters from the set [CAPF?] with which the shell informs the newly started program about how the logical file handles are currently used. The first character describes how handle 0 (stdin) is connected, the second characters describes stdout, and so on. The iovector string not only covers the six standard handles, but goes on to the non-standard handles as well. However, Mark Williams does not document how long the iovector should be. Their default value (used if the shell doesn't pass one) has a length of about 30 characters which to me makes no sensible number... Now, the meaning of the individual characters: A 'C' means the handle describes the console, 'A' stands for the auxiliary port (RS-232), 'P' is the parallel port, 'F' indicates a file, and the question mark either says the handle is not used or the shell itself has no further information about it (the docs are not clear concerning the '?'). For example, the default iovector is 'CCAP????????????....' (I don't know the exact number of question marks), meaning that stdin and stdout are connected to the console, stderr goes to the RS-232 port, handle 3 accesses the parallel port, and all other handles are not connected (or haven't been touched by the shell).

MWC provides three different startup code sequences. Two of them, to be used for .PRG and .ACC programs, ignore the iovector and the whole of the environment entirely, so you can change ARGV as you like, it won't get through to the program. The remaining code (crts0.o), to be used for .TOS/.TTP programs, scans the environment much the same as Atari's ARGV sample startup, with three significant differences:
a) It doesn't insist on an equal sign following the ARGV. (I haven't paid attention to that yesterday and therefore haven't checked it rigorously, but it seems to me now that MWC programs would go astray on an environment variable ARGV_EMPTY, stopping the scan after seeing the first four letters and assuming the argument vector follows.)

b) Provided the equal sign is present, the startup code stores the address of the next byte following '=' into the global variable `_iovector'. It doesn't check in any way what this byte or its successors contain. Hence, as far as the startup code is concerned, the ARGV environment variable might take any value. (But read on..)
c) No validation with the length byte in the command line is performed. It is no good, therefore, to call a MWC program from an ARGV-unaware program which in turn got started from a shell using ARGV (either Atari's or MWC's flavour).

Within the libc library of MWC, the iovector is referenced (through the _iovector variable) at only two places. One of them is `execve.o', a module that I haven't look into. The other is the module `_fhtype.o' that among others defines the function `_getfhtype'. This is referenced by about half a dozen functions (like `open', `read', etc) which expect `_getfhtype' to return the appropriate character from the iovector, given the file handle. If an 'F' is returned, they typically reference the file handling functions of GEMDOS, and the appropriate character device function if one of 'C', 'A' or 'P' was returned. This way, they bypass GEMDOS' redirection mechanism (broken in TOS 1.0 and 1.2). Now, what does `_getfhtype' do with an ill-formatted iovector? Either this string is too short to have an entry for the file handle in question, in which case the function returns an error flag, or the character sitting at the position described by the file handle is returned "as is" (no checking done). I haven't investigated how the calling functions react to the error flag or to a grossly wrong character, but I (and you) can see what happens when stdin is redirected to a file but the non-conforming iovector has a 'C' at position one: GEMDOS falls back to its own redirection mechanism and tries to access the file through the character device functions ==> failure on early TOS versions. Note that this is only one example, there are more ways to kiss the lion.

I hope this helps to clarify somewhat the MWC mystery. Keep the discussion on ARGV going, I am following faithfully.

```
* Fastest possible 32 pixel wide non-preshifted sprites???
*
*
* Entry:
* a0 = pointer to sprite data
* a1 = pointer to screen (place to draw sprite)
* d4 = # scanlines - 1
* d7 = shift (0-15)
*
* Exit:
* a0-a2/d0-d7 trashed
* a3-a6 preserved
*
* Sprite data:
* 10 words/scanline
* (mask)(plane0)(plane1)(plane2)(plane3) x 2
* Mask:
* 1 = sprite
* 0 = background
```

```
* Planes:
* Background pixels *must* be set to 1111
*
* How it works:
* Each piece of data is rotated once rather than being
* shifted so no data is lost. Data for current word
* is separated from data for next word by cookie cutting.
* Eg when shift = 3 cookie cut masks are:
* d5 = %00011111111111111000111111111111
* d6 = %11100000000000001110000000000000
* When two planes are rotated together, next word
* data for earlier plane ends up in low word and
* viceversa so a swap is needed.

Wow, our options shrink to nearly nothing at this point. If we can't use
escapes because they can be mistaken for real data in some situations, and
we can't do anything that involves a different validation to indicate an
extension to the standard, that pretty much leaves us with the value of
ARGV=.

Can anyone tell us *exactly* what MWC does with the value now? What does
it look like? What's it used for?

Perhaps you could combine the "new" argv value with MWC's. MWC uses
the argv string only to determine isatty() status, so few things break
anyway. MWC uses
ARGV="a string with characters giving each bios handle's status --
pointing to a file, a tty, or unknown".
Perhaps we could just append the null argument list after that string;
I doubt MWC checks the tail of the string.

Most likely though is that the amount of things that would break are
not worth the trouble. Most programmer's recognized MWC's isatty() as
a botch early on and used a more portable library function, replacing
isatty(). Hence, most compiled programs out there probably won't have
any problem with new ARGV definitions. I used gulam for years with MWC
compiled programs and even though gulam botched its MWC compatibilty mode,
I experienced few problems.

Well the current ARGV convention uses the length byte for validation, which
would mean that MWC compiled programs are already broken.

I've followed this discussion diligently (I hope) and I've re-read the ARGV standard.

It seems to me that the "best" solution is Eric Smith's which involves using the value of ARGV since it seems to meet everybody's criteria about not breaking programs which use the current ARGV standard.

However, from other posts, it looks like using the value of ARGV might break programs compiled with MWC since MWC uses it for an "iovector". It seems to me that most of the PD/Shareware tools, which I think are the programs which people would most likely want to pass in a null argument, in the archives have been (re-)compiled with GCC. So, using the value of ARGV won't be a problem there. Also, the programs compiled with MWC won't break unless it gets null arguments in the first place, which if I understand correctly, it couldn't handle before anyways.

So for programs compiled with MWC, we are swapping one broken behavior (most likely a truncated argument list) for another (the MWC startup code interpreting the list of null argument positions as an iovector and possibly cause some unpredicted mayhem) which happens only when we pass null arguments into those programs. In all other circumstances, they behave as they have before.

Except for the possibly unpredicted behavior, this doesn't sound like too terrible a trade off to me. Am I missing something? Are there more programs compiled with MWC to which a person would want to pass null arguments than I thought?

BTW, once there is a new standard, how do we get Atari to officially endorse it again?

Subject: RFD: comp.sys.atari.znet
Followup-To: news.groups,comp.sys.atari.st
Sender: jonc@status.gen.nz (Jon Clarke, Z*NET PC Assistant Publisher)

Request For Discussion (RFD): comp.sys.atari.znet

Status: unmoderated

This is an official Request For Discussion (RFD) for the creation of a
Usenet newsgroup called comp.sys.atari.znet

Charter:

Comp.sys.atari.znet is for discussion of all aspects of the ASCII Magazines
produced by Z*NET including feeds from Z*NET FNET (FoReM NeT, Gatewayed via
The Z*NET Global News Gateway "status.gen.nz") also including discussion on
all aspects of the following

- Atari Explorer On-line
- Z*NET PC
- Z*NET Fido echo's (Zone 3)
- Z*NET FNET

Topics would include those current discussed in the Z*NET FNET echo, GEnie,
Delphi, Compuserve, Bix, Fido and comp.sys.atari.st which cover Z*NET Topics

- Letters to the Editor
- Current issue feedback
- Columnist's reply
- Letters to the Z*NET Global Crew
- Atari Explorer On-line
- Z*NET PC
- Z*NET FNET echo's
- Z*NET Fido echo's (zone 3)
- Z*NET Pacific
- Z*NET Europe
- Z*NET USA
- Z*NET Canada

Topics will also include an open forum to discuss topics of interest with the
Director of Communications at Atari Inc, USA and will be open to all Atari
based computers ie 8bit Series, ST Series, PC Series etc. Feedback will be
gatewayed back to fido net and FNET thus allowing a great interaction of users
across three networks.

Discussion of this proposal should be posted to news.groups. As per the Guidelines, discussion that occurs there is the only discussion that counts. If your site does not carry news.groups, and you are interested in this discussion, get your administrator to carry the group.

Source record: 43187

perhaps we could only include [eric's] ARGV=NULL:... thing iff there are null args and leave it alone otherwise. this would seem to be least intrusive, tho somewhat more work in parsing (but not that bad).

if MWC's parsing of iovector is terminated by a \0 and we extend the CCAP??... string longer, this may have a problem if the array to hold iovector is only 30-whatever chars (we overwrite memory). if, on the other hand, the parser has a fixed loop (for(i=0;i<30;i++) or strncpy) we win. seems to be the last piece of the puzzle...

I moved it to 'gcc-cc1plus.ttp' (Unixmode) which works fine. Thanks to the
many people that answered the question!

3095. lc for MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-08 15:15:12 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Aug8.151512.14791@csi.uottawa.ca>
Source record: 43196

lc, an alternative file lister to ls, was just released on one of the sources groups (Comp.sources.unix, I think?).

The "big" thing about it that is good is that it separates the directory listing into sections, with "files" and "directories" and so forth.

As I learned to like it at U of Waterloo, I thought it prudent to see about porting it.

If you assume -DPOSIX, it works fine under MiNT. Unfortunately, it doesn't work so well under TOS. It'll RUN, but then does things like complaining "Can't stat <filename>" for each of the files being listed. Is there anything obvious that I ought to know about TOS that's abnormal, compared to MiNT?

Once it gets working, it'll certainly go up on the archive!

The correct termcap entry for tw52 is the one put into the TERMCAP=
environment variable by TOSWIN. You can also retrieve it by sending
ESC T to TOSWIN from one of the windows. These methods are to be
preferred over using a fixed /etc/termcap entry because (a) they
get the number of rows and columns right for the window, and (b) they
will always be up-to-date; if a future version of TOSWIN has new features,
those will appear automatically in the data supplied by that version
of TOSWIN.

I don't think that this has ever been documented. It may even (in fact, probably does) vary with different TOS versions.

One likely reason that it hasn't been documented is that, at least in current TOS versions, all handles >6 are "global", and so a program that tries to manipulate any handles that it doesn't own will wreak havoc on other programs (e.g. the shell used to launch it). So the value can't be used in a loop like
for (i = 6; i < MAX_HANDLES; i++) Fclose(i);
without causing big problems.

Also, the number of handles available for use by a given program will vary with how many handles are in use by its parent and grandparents.

It's best to just treat the numbers returned by Fopen() and Fcreate() as "magic" numbers, and not to try to rely on any structure (e.g. don't assume that they're in a range like 0..N for some N). In particular, it's best not to use them as indexes into an array, unless you're careful to check for out-of-bounds handles and have a way for your code to work on these (perhaps with some loss of speed). In this case, I would recommend a _minimum_ array size of 32 (the number of private handles available under MiNT); 64 would be a more general number (it roughly approximates the maximum under most versions of TOS) and 256 would usually be enough for even odd cases like MiNT global handles and MetaDOS handles; but again, make sure your code can deal even with handles >256, since there is no guarantee that these can't occur!

I have the problem that although the mouse cursor moves nicely on the screen, the AES apparently goofs up as you can witness in the following program. In the program, the second graf_mkstate call never gets the right X value, also the y value looks right.

I have TOS 1.4 BTW.

```
-----------------------------snip-------------------------------------
#include <stdio.h>
#include <stddef.h>
#include <aes.h>
#include <vdi.h> /* Pure-C include files */
#include <ext.h>

int aes_id, /* AES application ID */
vdi_id; /* VDI ID */

static int work_in[ 16] = { 1, 0, 1, 0, 0, 0, 0, 0, 0, 0, 2 },
work_out[ 64];

void init_stuff()
{
int dummy;

aes_id = appl_init();
vdi_id = graf_handle( &dummy, &dummy, &dummy, &dummy);
v_opnvwk( work_in, &vdi_id, work_out);
vst_color( vdi_id, 1);
}

void done_stuff()
{
v_clsvwk( vdi_id);
appl_exit();
}

typedef struct
{
long type;
int x, y;
} APPLRECORD;

static char buf[ 80];
```

```
main()
{
int i;
int x, y, nx, ny, foo;

init_stuff();

/* just to show that the graf_mkstate C-binding is working */

v_gtext( vdi_id, 0, 16, "Beweg' dat M�usken");
for( i = 200; i--;)
{
graf_mkstate( &nx, &ny, &foo, &foo);
sprintf( buf, "Check: X: %3d Y: %3d ", nx, ny);
v_gtext( vdi_id, 0, 32, buf);
}

/* now position mouse and try to get the position from AES */
for( x = 0; x < 320; x += 32)
for( y = 32; y < 160; y += 16)
{
sprintf( buf, "Positioned @: X: %3d Y: %3d ", x, y);
v_gtext( vdi_id, 0, 16, buf);
pos_mouse( x, y);
graf_mkstate( &nx, &ny, &foo, &foo);
sprintf( buf, "AES reads : X: %3d Y: %3d ", nx, ny);
v_gtext( vdi_id, 0, 32, buf);
for( i = 20000; i--;); /* just wait a bit */
}
done_stuff();
return( 0);
}

pos_mouse( x, y)
int x, y;
{
static APPLRECORD buf = { 2, 0, 0 };

buf.x = x;
buf.y = y;
appl_tplay( (void *) &buf, 1, 100);
}
------------------------------snip-------------------------------------

When I use v_dspcur on the AES vdi handle, I can position the mouse
pointer nicely, but the AES doesn't recognize it.

Any comments ?
Hope I didn't miss something terribly obvious.

Nat!

NO!
Real sprite code IMO must save the background else it's merely a
blockcopy with a mask.

>* Entry:
>* a0 = pointer to sprite data
>* a1 = pointer to screen (place to draw sprite)
>* d4 = # scanlines - 1
>* d7 = shift (0-15)

Yikes! you don't want to shift 15 times or in your case rotate. What would
be better are 4 different cases. One is 'shift = 0', then you can forget
about the shifts, one is 'shift = 8' (then you just use byte addressing)
the other two cases are 'shift < 8' and 'shift > 8'. In the case of the
first your code will do, in the latter case you just rotate the words in
the other direction with d7=16-d7 rotations for words and for longs you
use this:

move.l (a0)+,d1 ; get planes 0 & 1 of sprite
swap d1 ; rotate 'em 16 times
rol.l d7,d1 ; rotate back

Nat!

Organization: Nyx, Public Access Unix at U. of Denver Math/CS dept.
X-Disclaimer: Nyx is a public access Unix system run by the University
of Denver for the Denver community. The University has neither
control over nor responsibility for the opinions of users.

I'm inclined to agree with that summation: MWC programs can't deal with
null args now, so if we do something with the ARGV= value to support null
args, then passing null args to an MWC program still won't work, and that's
no big deal really.

It would be nice if we could be careful not to cause any really outrageous
behavior in an MWC program that does receive unexpected values in ARGV= due
to the presence of null args. Perhaps putting 32 chars of iovector info
there would be safe in 99.999% of the cases (since a parent program is pretty
unlike to fire up a child program while it has 32 files open, I'd think).

I sent a message to Atari about modifying the ARGV standard, and I'm gonna
send a followup summarized what we've discovered recently here. I don't
expect a quick reply from them, they don't log on to BIX all that often
anymore, but they are aware that we're discussing the issue.

> how many DOS handles

I think I once determined experimentally that TOS 1.0 would give you up
to 64 handles, but it was long ago, I could be remembering wrong. Anyway,
it's easy enough to write a program that just keeps opening a file until
GEMDOS reports an error.

> it's best to treat [the handles] as 16-bit magic numbers.

Yes! In fact, the GEMDOS manual says that pretty clearly the way I read it.
I once wrote a special file caching program that hooked Fopen/Fcreate/etc,
and fielded some file opens without passing them to DOS. I would return
a psuedo-handle in the range of 16,000 - 32,000 for the file, then field
all I/O requests on those handles. A surprising number of programs broke
when they got back a handle in that range (emacs comes to mind), but this
was way back in 1986/87, when (presumably) folks didn't know any better
and felt safe assuming a handle could index into an array or whatever.

I ask the question because I want to define OPEN_MAX and _POSIX_OPEN_MAX
in my limits.h file for my library.

OPEN_MAX can be indeterminate for a given implemenation, but _POSIX_OPEN_MAX
is the minimum value a implementation must be able to support which is 16.

I just want to make sure that TOS has enough.

Hmmm. As I mentioned, all the handles are global (that is, if TOS has a limit of 64 handles, and process A uses 63 of them before launching process B, then process B can only use 1 handle). So, strictly speaking, TOS may not be able to provide enough. (Yet another way in which TOS is not POSIX compatible...). In practice, this doesn't happen very often.

I suspect that this behaviour will be changed in MultiTOS. The MiNT kernel has an array of 32 file handles for each process, so it would make sense to #define OPEN_MAX 32 in the MiNT environment (and indeed, that's what the MiNT library does). Since this is comfortably below TOS's global limit, I'd say that it's a good value to pick.

>Hope I didn't miss something terribly obvious.

I haven't tried your code, but I can make a number of general comments.
In trying to substitute a digitizing tablet for a mouse I've become more
of an expert on AES and mouse positioning than I like, but there are still
a number of things that I find difficult to explain.

You must keep in mind that AES is geared to interaction with
the user's program through events, in particular through evnt_multi().
Any other interfacing functions are are quite likely to behave unexpectedly.
The graf_mkstate() function you show is an example: it is possible
that the info for graf_mkstate() is simply not updated when you use
appl_tplay(). Quite likely the authors of GEM do not even consider this a bug
since they consider the appl_tplay() instructions to be events that can
only be received through evnt_multi() and friends, and not through
graf_mkstate().

AES is riddled with such silent assumptions. In short, don't stray from
the beaten path: use evnt_multi().

Yes, I agree this is a bug or at least an error in the design, but
who ever said that AES and VDI were good designs?

3105. Launching an application in a TOSWIN window

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-09 21:35:26 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <1992Aug9.173526.1@uwovax.uwo.ca>
Source record: 43207

I've received some queries about how to launch a TOS program in a TOSWIN window (under MiNT, of course) from another program, e.g. a CLI. Below is a sample program that does this. It's very rough and could use refining; I'll leave that to others, since this particular issue doesn't particularly interest me (and I have lots of other things to keep me busy!)

```
/*
* runtos: a small program that will launch a TOS or TTP program
* in a TOSWIN window.
* To compile:
* gcc -O -mshort -o runtos.prg runtos.c -lgem16
* To run:
* runtos someprog.tos arg1 arg2 arg3
* OR
* Using the desktop, do an "Install Application" on runtos.prg.
* For "document type", use .TOS. Now, double clicking on a TOS
* program will automatically start it up in a TOSWIN window.
* (unfortunately, it will also cause all TOSWIN windows to be
* hidden -- you'll have to select "TOS programs" from the DESK
* menu to get them back again).
* BUGS
* See above. Also, it would be nice to have a "runttp.prg"
* that would prompt for .TTP arguments. This is left as an
* exercise for the interested reader.
*
* "runtos" was written by Eric R. Smith and is hereby placed in
* the public domain.
*/

#ifdef __GNUC__
#include <minimal.h>
#endif
#include <osbind.h>

long _stksize = 2*1024;

int
main(int argc, char **argv)
{
static char buf[1024];
char *where = buf;
int i, fd;
long r;
```

```
if (!argv[1]) {
Cconws("Usage: runtos program [arguments...]\r\n");
return 2;
}

/* construct the TOSRUN request:
* first, the current directory...

From: bussche@ksla.nl
Message-ID: <01GNF2ZMRU8W8WZ2VQ@ksla.nl>
Source record: 43210

Hello! I'm going to add some hardware to my ST. I need more serial lines. There is an internal signal called 'dev' (or /dev) which seems to indicate that the processor is accessing adresses in the I/O region $FFxxxx. Can anybody confirm that? Since there are a lot of not used addresses there, it should be easy to use a few for ACIA's. The interrupt routine in the roms (2.06) is very straight forward, so hooking in a few extra control registers to poll looks feaseble. Any comments/replies??????

P.S. I cannot read the newsgroup directly (yet), will have to wait until things show up in the DIGEST.

Thanks, Egbert Jan van den Bussche (bussche@ksla.nl)

Sorry, no fancy signature...

(Eric Smith) writes:

Along with the MiNT executables is provided a beta version of TOSWIN,
a really nifty (well, I think so :-)) new window manager that can work
as a .ACC. Unlike the old BGACC, this one supports arbitrary GDOS fonts
(including proportional fonts!), scrollback (like xterm), and allows
for dynamic resizing of windows.

Has anyone else had the problem of toswin corrupting the fonts used by other programs? I'm running Gemini v1.2 , and Rufus for comms. Rufus normally puts a status line at the top of the terminal in the 6x6 system font, and this seems to come out as the 6x6 font, but in about 16x16 pixels. Looks horrible and ruins the idea of the status line, as it goes off screen.

I *like* Rufus, it's a very nice 'comms-in-a-window' accessory, though I've only used it for a short time. I'd not much like to get rid of it. Toswin also seems to interfere with GEMini

Do I have to get rid of my favourite programs to use MiNT ? (say No! :-)

Simon.

Yeah, you can have versions optimised for each shift amount. The only thing is
that you need specialized versions to handle the screen edges anyway and all these
specialized versions multiply up. It depends on how much code you're
prepared to have - you could unroll the whole thing into linear code or have
versions specialized for individual sprites - but then we're almost back to
preshifted sprites. I think a good compromise is to just have the 4 cases you
suggest for mid screen sprites and have a single "shift right" version for each
of the 4 (2 left, 2 right) edge cases.

I still reckon that rotating & cookie cutting beats other multibit shifting methods in the
general case.

Steven

>
Starting the ARGV value by literal "CCAP?????..." (I've taken a count now:
there are 24 ?-characters, odd number I say) is ok in the sense that it's
not making matters worse. That is to say that an MWC program that behaved
well in a non-MWC environment (where it had to rely on its default iovector
which has exactly the above format) should also run ok under the new scheme.
Of course, it is not ok in the strict MWC sense, as it is not providing the
information on redirection that it should. Redirecting stdin to a file for
example is (under old TOS versions) disastrous with this fake iovector but
again this would also happen with no explicit ARGV value given.

I don't see any problem in appending something new (like "NULL:....") to
the end of the fake iovector. The ARGV value doesn't get copied to a
reserved memory area, MWC leaves the information in the environment so
that memory overflow is not a problem.

True, in that they violate the ARGV conventions. Currently, this is only
fatal when an MWC program sees an ARGV=... that was not intended for it.
Other than that, it would properly decode an ARGV assembled by a conforming
shell. If we have different flavours of ARGV distinguished only by the
length byte, MWC programs will have the additional difficulty of finding
superfluous spaces or tildes in the arguments.

Be careful, don't choose this name. All environment variable names
starting with ARGV -- irrespective of what follows -- are taken as
THE ARGV by MWC programs because these don't check for the '='
character. The rest of the environment will be interpreted
according to the old rules.

Check out Atari's latest GDOS incarnation, FontGDOS. I'm not sure if it's
at atari.archive, but I hope it is. It has a DJ500 driver in it.

I tried all combinations and without other stuff in the auto folder etc.
Without success. Then I tried a minimal MiNT configuration on my old ST:
TOSWIN had no problems!!
So this is definetly a TT-only bug (or feature :-), and other German TT users
reported the same behaviour. If you could get a hand on a TT and look after it,
many TT owners would thank you very much, Eric.

Regards, Markus.

Taking the MegaSTE back to the dealer is great if there is
one within 100 miles! There is almost no ST support in the area
I live in, we have a huge wholesaler here but that is not open
to the public.
I find myself in the same situation as J.J. Lehett, a
worthless 1.44 Disk Drive.
To think Atari put this crap on the market makes me ill, I
guess Quality Control is non-existant or they only give a shit
about making money and figure 'Hell with the consumer, I bent
him over already'. At least I know not to but an Ajax chip, new
TOS or another Atari product. And I have and will make sure I
discourage anyone from buying Atari and go with IBM or Amiga!

>Do I have to get rid of my favourite programs to use MiNT ? (say No! :-)

Some programs become pretty meaningless once you use MiNT. Who needs Rufus,
when you can run any-old terminal program in a window/in the background?

My modus operandi is to fire up Uniterm, auto-login, quit-uniterm, then
just use a really DUMB "terminal program" (home-made con <-> aux
echoer), run rz in the background (with:

ulimit -d 160K; /mint/bin/bg -o rz.out rz; ulimit -d unlimited

), then do some more work. If you have a screen-accelerator, and better
eyes for small fonts than I do, TOSWIN would effectively give you Rufus,
by running say "TIP" (the vegetable-simple term prg) in a window.

After all this time collecting nifty programs, all I want now is some
SIMPLE programs!!

*** Aside HINT: ***
Some programs that you used to think worked okay with the "fast" bit
set may not really have worked - and they seem to show up under MiNT.
(eg. the grep I am using). So if a program doesn't work, clear the
"fast" bit, and try it again.

>by sprite basis, interleaved with drawing the sprites is not one of them.

Well, IMO, it IS the best method, for these reasons:

1. Encapsulated (don't need some GLOBAL background map)
2. Allows for different update frequencies of different sprites
3. Memory efficient
4. Fast

No, you say "Yuk", but give no alternatives. So I will:

1. XORing.
- This one is hopeless, it's only possible advantage
is that it is more memory efficient
2. Keeping global background
- This one is too dependent on the application to
be viable as a general scheme. For example, it
works okay for a static background, but once you
start animating the background, your CPU-load
massively increases as you keep having to update
both the display images and the backgrouind store.
3. Assumptions about background
eg. Background always blank. Hardly worth mentioning,
but definately the fastest sprite-erasing technique.

>that you need specialized versions to handle the screen edges anyway
>and all these specialized versions multiply up. It depends on how much
>code you're prepared to have

The more specialized versions the better. The way I work is to create
new versions on an as-needed basis. If I really need the speed gained
from a 1-bitplane sprite over a 4-bitplane one, I'll add that class to
the library. So far, I only support STLow, STHigh, TTMedium, and
TTHigh, preshifted 16-bit, 16-bit, and 32-bit sprites - but if I need a
STMedium sprite, I'll code it up - it's only a few dozen lines of asm,
just for the non-generic portion - everything else is inheritted from
the more general classes. Of course, if C++ isn't your game, you'd be
crazy to implement more than 4 of 5 special cases, keeping them
as generic as possible... and slowing them down... hooray for C++,

<etc. on the religious stuff>

3120. Reopen an ACCs window ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-11 06:13:41 UTC
From: mfg@gmd.de
Message-ID: <mfg.713513621@gmd.de>
Source record: 43221

I would like to know if there is a clean way of _automatically_ reopening the windows of an Accessory after they have been closed by starting or terminating an application. The simple solutions of either instantaneously reopening the windows or sending a AC_OPEN request as reaction to a AC_CLOSE seem to cause problems with a number of applications. Sometimes the desktop seems to be cleared _after_ the reception of the AC_CLOSE and even _after_ the processing of a following (self-made) AC_OPEN message. As a result the window disappears and the window-manager gets confused. BTW: My ACC closes and reopens the virtual workstation and recreates the windows. So there are no problems when I reopen the ACC manually from the menu-bar again.

Thanks,
Martin Gergeleit <mfg@gmdzi.gmd.de>

3121. Gemini vaproto: ASKCONFONT, does it work?

Message-ID: <9130027@hpbbrd.bbn.hp.com>
Source record: 43234

(I took a bit long to respond, but the responses to my original post didn't arrive until today).

All the proposals that include '\0\0' sequences into ARGV won't work. Remember, ARGV is part of the environment and '\0\0' is the environment terminator. Pexec() just won't pass anything after that to the child process.

From what I have seen, the approach using additional spaces seems to be the simplest. I'm voting for it.

Jens.

The real problem with this method is when sprites overlap - then doing the right
thing gets complicated & slow. If you aren't replacing the background thru
the (possibly) shifted mask (which is slower) the sprites don't even have to
overlap - just the 32x32 (or whatever) rectangles.

|>
|> No, you say "Yuk", but give no alternatives. So I will:

I believe STOS does this. If you have lots of sprites and comparatively little
background movement then this can win.

|> 3. Assumptions about background
|> eg. Background always blank. Hardly worth mentioning,
|> but definately the fastest sprite-erasing technique.

How about:
4. Wipe all sprites, Save under new positions, draw all sprites etc.
Okay you need to double (better still triple) buffer to avoid
flicker but its fast & you can decide on sprite priorities
& handle overlapping sprites correctly.

5. Redraw background, draw sprites, redraw background,... etc
Really only viable if the whole background needs to be redraw each
frame (say you're software scrolling the background or have a
3D vector background).

IMHO the best way the handle background is dependant on the number of sprites
& the nature of the background. For this reason I prefer the keep the "save under"
code separate from the "draw sprite" code so one can choose whether & when
to use it. The "several good ways" I had in mind were 4, 2 & 5 in order of
preference.

Do you have seperate code for each "partly off the edge of screen" case (actually
you only have to worry about the left & right edges)? That must multiply up
to quite a bit of asm.

> a desk accessory that can automatically reopen its windows

This is a hard one. I did it once, and it worked in all situations *except*
when HotWire was installed. As usual, the codehead software was doing so
many dirty things to the system that I just couldn't find a way to peacfully
coexist with it.

Here's some things (from memory of a project 4 years ago) that might be
helpful...

When the ACC starts, get the process ID value for the desktop buy examining
the TOS _run variable. Later, when you get an AC_CLOSE and want to do a
reopen, you can get the current process id value again, and compare it to
the desktop's id you got at startup, to see if this AC_CLOSE is being done
as a return-to-desktop operation.

It's possible to get multiple AC_CLOSE messages in your event queue at
once. Since AES doesn't have a PeekMessage() function to look ahead in the
queue, you have to roll-your-own with a loop that gets each message, looks
at it, then requeues it with an appl_write().

When you do find an AC_CLOSE that's a return-to-desktop, don't directly
reopen your window. Instead, delay about 500ms then send yourself an
AC_OPEN. This'll give the desktop a chance to get itself settled and get
its windows open before you try to open yours again. When the AC_OPEN
comes back in to you, note what the top window is, then open your window,
then do a wind_top() passing the handle of the previously-open window
(unless you really want the acc's window to be topped on every return to
the desktop).

I suspect it'll be nearly impossible to write a version of this that'll
work in all situations -- all versions of TOS, coexisting with codehead
and other dirty TSR software, and so on. Coexisting with non-AES desktops
is a whole 'nother ugly issue that I didn't even attempt.

Good luck!

>Yeah, you can have versions optimised for each shift amount. The only thing is
^^^^^^^^^^^^^^^^
Since tables are pretty much out of the question (you only have 24 address
space in a ST, you'd need 32) I don't see what you want to optimize "for
each shift amount" that's not either 0 or 8. Maybe I am just clueless though.

>I still reckon that rotating & cookie cutting beats other multibit shifting methods in the
general case.
It's a nice method for sure. I (since I have memory to blow) always pre-shift
'em.

3129. TeX

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-11 21:55:03 UTC
From: pwp@moose.cs.indiana.edu
Message-ID: <1992Aug11.215510.8450@news.cs.indiana.edu>
Source record: 43227

I am having two troubles trying to get TeX running.

On an Mega ST (4 Meg of memory, TOS 1.2) all is fine until I run
tex.ttp plain -i
(This program is from atari.archive.umich.edu, atari/tex/tex31/texbin.zoo).
I get the following two lines:
! I can't read tex.pool.
cmd exit code 1

I am running from gulam in directory e:\tex. In that directory I also have
tex.ttp, tex.poo, and plain.tex (as well as a number of other files).
When I do setenv in gulam, I get

TEXPOOL=.=

(along with a lot of other stuff), which is as expected.

On my 520ST (1 Meg of memory, TOS 1.4) I appear to just plain run out of
memory, even when I run from the desktop. (From the desktop tex starts up
just fine if I leave off the -i option.) The file readme_e.tex suggests
that I should not quite be out of memory. I am running a Supra hard disk
with and no desk accessories. The autofolder has poolfix3, the hard disk
booter and nothing else. The second problem is not so serious as the first
one. Once I get my format files (from either machine) I no longer need to run
with the -i option. Still, if I don't have my memory as small as possible, it
would be nice to know what else I can do.

The correct termcap entry for tw52 is the one put into the TERMCAP=
environment variable by TOSWIN.

Thanks, I got this one figured out. Part of my confusion came from the
fact that I tried to get TOSWIN working before my system configuration
was set up properly, and I ended up corrupting my copy of the binary.
After reinstalling TOSWIN and setting up my shells correctly, it works fine.

Has anyone considered a menu compiler for TOSWIN's .mnu files? I have
started work on one, but I'm not sure what the user interface should
be. I could use GEM or a CLI front end, and if I chose GEM the
program should probably be a DA. It would be easier to get the data
from the command line than from a file, because the VDI keycodes are
generated by the user's keystokes and returned by the BIOS. If I get
the program to read in files, I will need a translation table.

All suggestions are welcome.

3133. Can a TSR Malloc()?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-12 05:06:33 UTC
From: sourada@iastate.edu
Message-ID: <sourada.713595993@vincent1.iastate.edu>
Source record: 43233

Is it possible (and good practice) for a TSR program to Malloc()
(the GEMDOS way) after Ptermres()? I'd suppose it's either not possible
or not something you should do, but I've thought that about other things
also :-)...

BTW, the way the TSR would get control (the way I'm thinking of) is:
another program (or accessory) would jump through an address found in
a cookie.

Of course, this would leave GEMDOS thinking that the invoking program
was the Malloc()er, but it's probably possible to inform GEMDOS of who
the real caller is. Whether that's a good idea...

Later,

Bug in TOSWIN...

I've noticed that the pop-down menus always pop down even if the window they're associated with is not the "top" window. Shouldn't they be deactivated if the window that they refer to is not the current window ? Or is this a design feature, because of the multi-tasking nature of TOSWIN ?

In fact, I'm using NVDI 2.03 on my (North American) TT with TOSWIN, and
haven't had any problems.

I've also tried a variety of different GDOS's with TOSWIN, and they've all
worked fine.

Perhaps there is a bug in the German version of NVDI? (The one I have is all
in English.)

Personally, I think that this is a bug in GEM (it shouldn't be sending mouse events to a program that doesn't have control of the mouse). At any rate, I will change TOSWIN's behaviour -- this bug has been reported by many people.

No, and no.

Or, more accurately, it's possible, but not likely to produce the desired effect. As you point out, GEMDOS will think that it's the invoking program that did the Malloc, and will free the memory when the invoker exits.

There is no reliable way to make GEMDOS change the memory ownership of Malloc'd memory. The tricks people use to do this *will* break in future versions of TOS (in particular, MultiTOS) and neither will they work under MiNT.

3142. Re: Null arguments with ARGV

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-12 16:30:35 UTC
From: jvt@its.bt.co.uk
Message-ID: <1992Aug12.163035.9518@its.bt.co.uk>
Source record: 43243

I have been following this thread with more than a little bemusement at the intricasies of passing args through TOS. Probably the way to have avoided all of this would have stored the *argv[] array in the parent and passed a pointer to the child, yes in the environment if you have to!

However, we do not have a clean slate so compatibility must be paramount. First we must consider that old applications being passed a null arg will fail anyway. That means we only need consider new applications as long as we leave ARGV untouched.

So now we must mandate a new variable (say ARGN --- call it what you want) which will hold pointers to the null args.

> app arg1 "" arg3 "" arg5

wil produce
ARGN=2,4
ARGV=\bin\app\0arg1\0arg3\0arg5\0\0

All we are left with is the "validity of ARGN" problem. Well, since GEM only copies the environment up to the first \0\0, then ARGV **must** be the last entry in the environment for this mechanism to work. Similary for the exec mechanism to work, ARGN will be the penultimate entry and for it to be valid
(getenv(ARGV) == (getenv(ARGN)+strlen(getenv(ARGN))+6))
Now this is not perfect as a non conforming application that execs could pass on ARGN and ARGV in that configuration and so lead to chaos. Conforming applications could remove the ARGN value after use on startup which would limit the damage but its only really a partial cure.

Umm, coming back to the conclusion that all existing applications could potentially break, then there is little mileage in trying to bend the existing method to cope so why not consider a new method that will run alongside the existing argv? If the *argv[] array was stored in the child and pointed to the strings (or WHY) in the exec call, the address of argv could be passed as a hex represented string in the environment along with the current ARGV. The cost penalty is low at 4n + 4 bytes + new env variable. This should be alright as long as a child does not outlive its parent (MiNT etc?).

Hope I've provided some food for thought.

John

> can a TSR Malloc()
> [basically no, because the wrong process would own the memory]

I've always thought it should be possible to temporarily change TOS's _run
variable temporarily so that it points to the TSR's basepage during the
Malloc() then gets set back to the proper value. But, I've never tried it,
it just seemed like a possibility to investigate (despite the fact that
Atari warns you to "look but don't touch" on that variable).

> any current tricks will break under MultiTOS and MiNT

Well then Shame On You for not fixing this problem, Eric. Don't you know
we've all been counting on you to undo absolutely every bad design decision
Atari initially made? :-)

Seriously, though...it would be nice to have an alternate form of Malloc()
usable by TSRs and desk accessories...something where you could pass a
pointer to the basepage of the process that should own the memory.

You can also adapt this method for horizontal scrolling by arbitrary number of pixels. Of
course if shift % 16 = 1,8 or 0 specialized methods will be faster.

Steven

>

I would assume that the situation he is referring to (J.J.'s = me)
is that I have a TOS 2.05 MSTe that came with a 1.44 drive. It didn't
work, and I posted about this a time or two. I upgraded to TOS 2.06, and
even replaced the Ajax chip thinking it could be defective, so... with these
improvements I 'in essance' should have a reliable 1.44 drive. This is not
the case. I have pulled the power supply screw, I have unhooked the Hard Drive
from the power supply to avoid any interference from the power lines, and
I continue to always get a error upon formatting at track 45 when in HD mode.
Yes, I have tried numerous high quality HD disks.
I have been able to on occasion format a disk on an IBM and bring it
home and read all 1.44 megs succesfully... but never get a successful format
from the desktop.
I have been told that its really sound like an interference problem,
but with the error occuring at track 45 on formatting no matter what disk
I am using, this doesn't sound like it could be random interfernce, not to
mention that I have as I said pulled the power to the Hard Drive to reduce
the interfernce and still the same repeatable error. Diamond Format reports
the error as a cannot seek track error (I think that was it). Once it hits
track 45, you can hear the head going back and forth attempting to 'seek' the
track to no avail, and then it errors out.
Always on the lookout for more things to try, I have tried just about
everything that has been suggested so far, and I do not have another MSTe
available to try to swap mechs unfortunately.

> I've always thought it should be possible to temporarily change TOS's _run
> variable temporarily so that it points to the TSR's basepage during the
> Malloc() then gets set back to the proper value.

Aack! No, don't do this (it's precisely this "trick" that I warned you would break!). I think this is exactly why Atari warned people not to change _run. (If you're interested: MiNT doesn't use _run at all for memory management, because MiNT doesn't care about basepages, only about process id's -- this allows for funky things like fork() and vfork().)

> Seriously, though...it would be nice to have an alternate form of Malloc()
> usable by TSRs and desk accessories...something where you could pass a
> pointer to the basepage of the process that should own the memory.

There's a much better solution -- don't TSR! If your program is running under MultiTOS or MiNT, it doesn't have to terminate in order to stay resident; it can just run in the background. It can then do Malloc or file calls with no problems. If it wants to install some code in a vector that other processes can use, that code should use one of the (many) inter-process communication methods to send the Malloc request over to the "main" application which is hanging around in the background.

The Ptermres() call was a rather ugly hack that Microsoft invented to make up for the lack of multitasking in MS-DOS. I think it's outlived its usefulness.

3147. VT102 tip for MiNT?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-13 05:05:11 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Aug13.050511.19143@csi.uottawa.ca>
Source record: 43247

I'm playing with Howard Chu's tip program (is that short for "terminal interface program?" It would make sense...), and have a quick question.

It uses the "standard" Atari implementation of vt52-like features. Is there something out there that will do vt102? I'd really like to be able to use Emacs remotely, and for things to have "inverse" mode, and all the other "good" stuff that vt1xx modes give you (partial screen scrolls, I believe?)

I can live with Uniterm... I've been enjoying it for a LONG time... Any new version of tip won't likely have Kermit, which would be a big minus as compared to Uniterm.

But it would sure be nice to have an in-the-window terminal under MiNT that does a little better than vt52...

Now, for a totally unrelated question: Has anybody seen a standalone Kermit for the ST? Other than the desk accessory, which does NOT work very well? If there was source code for the UNIX version kicking around, we might be able to have C-Kermit running, which would be pretty neat!

> store *argv[] in the parent, pass a pointer to it

It's been done; it's called xArg. And quite a nice little standard it
is too, very clean compared to ARGV.

The problem is, Atari declared it to be anathema to multitasking OSes
they had planned (but not announced) at the time: they didn't want child
programs poking about in the parent's memory region, and quite rightly so
under a multitasking OS that makes any attempt at isolating applications
from each other for fault tolerance.

Hi All,
I've just got my September issue of Atari ST User (UK Mag) and in it
there is a 1 page preview of the Falcon including pictures! I cannot
comment on the authenicity but it will be interesting to compare notes
with US & D.

OK, here are the details from the mag:

first models expected in UK September
to be shown at London trade show - September 6.
68030 @ 16 MHz
DSP56001
8 channel 16 bit digital DMA, sampling up to 50KHz
4 channel stereo with recording and playback
262,144 colour palette
Max res 640x480 16 bit mode (65,536 colours on screen)
SVGA modes up to 256 colours on screen
Overscan mode (no black border)
15bit overlay mode for video titling etc.
MultiTOS
1.44 MB Floppy
IDE port for internal 2.5in 44MB hard drive
RAM: 1,4 or 14 MB
Optional 68882
Expansion slot for 386PC emulators or JPEG and MPEG data compressors
Ports
SCSI II with DMA
stereo microphone
audio out
monitor
midi
hi speed LAN (no they don't say what)
Joystick & analog joystick
printer port ``more industry standard''
working name was Sparrow
50 machines worldwide many at top software houses in UK (I presume
others are in D :-))
Atari Germany ``at least one model above and below Falcon030 including
68040''

rumours
price == 499 UK pounds
new case design next April

Sounds good if its accurate but some of the statements get me a little worried.

>The correct termcap entry for tw52 is the one put into the TERMCAP=
>environment variable by TOSWIN. You can also retrieve it by sending
>ESC T to TOSWIN from one of the windows.

If I open a TOSWIN window with MINTSHEL running inside, 'echo ESC-T' bombs out
the shell; I finally tried it on a minimal system; nevertheless the
problem didn't disappear:

This is a MEGA-ST1 with (German) TOS1.4.
I prepared a disk with only the following files on it:

AUTO\MINT.PRG
TOSWIN.ACC
TOSWIN.RSC
MINTSHEL.TTP

After system startup, open TOSWIN, create a std window with MINTSHEL in
it (no args) and enter 'echo ESC-T'.
In response, I get something like
pid 3 (MINTSHEL): BUS ERROR: PC=456205c (basepage=759d0)
The TERMCAP string gets printed, then MINTSHEL exits.

I've noticed with my TT that if I remove the HD and place it as far away as the cables will allow still connected, (HD = Hard Disk) my floppy gets a lot less errors, especially during writes. I've tried shielding the floppy cable from the HD and it helped but didn't cure the problem, but it might for you. Give it a try.

i seem to recall seeing an atari document that used the same name:
here is what i have from the gcc gemlib: it should be easy to adapt to whatever: (__MSHORT__ is defined when compiling for 16 bit integers)

```
int
vq_gdos(void)
{
register int retvalue __asm__("d0");

#ifdef __MSHORT__
__asm__ volatile
(" movw #-2,d0
trap #2
cmpw #-2,d0
sne d0
extw d0"
: "=r"(retvalue) /* output */
: /* no input */
: "d0", "d1", "d2", "a0", "a1", "a2" /* clobbered regs */
);
#else
__asm__ volatile
(" movw #-2,d0
trap #2
cmpw #-2,d0
sne d0
extw d0
extl d0"
: "=r"(retvalue) /* output */
: /* no input */
: "d0", "d1", "d2", "a0", "a1", "a2" /* clobbered regs */
);
#endif
```

```
return retvalue;
}

/*
* return type of GDOS
* -2L no GDOS installed
* 0x5F46534DL '_FSM' gdos
* 0x5F464E54L '_FNT' gdos
*/
unsigned long vq_vgdos(void)
{
register unsigned long ret __asm__("d0");
__asm__ volatile ("
movq #-2,d0

>the right thing gets complicated & slow.

Complicated? All you do is push them onto a stack when you draw then,
and pull them off to get the wiping order. Usually, it is sufficient
to just do it with code, rather than doing it dynamically:

while (1) {
Sprite1.Wipe();
Sprite2.Wipe();
Sprite3.Wipe();

Sprite3.Draw();
Sprite2.Draw();
Sprite1.Draw();

Pages->Flip();
}

>If you aren't replacing the
>background thru the (possibly) shifted mask (which is slower) the
>sprites don't even have to overlap - just the 32x32 (or whatever)

I can't believe anyone would ever consider replacing the background
through a shifted mask!

>background movement then this can win.

I believe STOS is a slow, hacky pile of sh!t... Have you seen some of the
programs written with it - ewww, chunky-slow to the max!

>How about:
> 4. Wipe all sprites, Save under new positions, draw all sprites etc.

This is exactly my #1 method, except mine is encapsulated.

You are saying:
for each sprite 1..n { sprite.Wipe }
for each sprite 1..n { sprite.SaveUnder }
for each sprite 1..n { sprite.Draw }

I am saying:
for each sprite 1..n { sprite.Wipe }
for each sprite n..1 { sprite.DrawAndSaveUnder }

My method is superior, simply because I get the sprite.SaveUnder almost
for free: YOU ALREADY HAVE TO READ THE SCREEN IN ORDER TO DRAW THE SPRITE,
so you may as well store that read data as you draw, saves reading twice.

> Okay you need to double (better still triple) buffer to avoid
> flicker but its fast & you can decide on sprite priorities
> & handle overlapping sprites correctly.

Obviously you have to double buffer. Any program that doesn't double-buffer
is a hack. (BIG smily!! -- Even Shift doesn't double-buffer - but I love it)

>IMHO the best way the handle background is dependant on the number of
>sprites & the nature of the background. For this reason I prefer the
>keep the "save under" code separate from the "draw sprite" code so one
>can choose whether & when to use it.

While I prefer to write code that works well in the general case :-)

>Do you have seperate code for each "partly off the edge of screen"
>case (actually you only have to worry about the left & right edges)?
>That must multiply up to quite a bit of asm.

Haven't had any need for a ClippedColourSprite yet. When I do, it will
only be a small matter of coding up the one sized clipped version.

Which reminds me - was this a competition? I wrote some VERY fast
sprite routines in a furious discussion with Dave B. - 60 or so
single-bitplane 16x16 sprites at arbitrary positions on an arbitrary
background was I believe my limit...

3163. Trapping ^C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-14 07:10:27 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Aug14.071027.24659@mnemosyne.cs.du.edu>
Source record: 43259

What's a good method of trapping a ^C from within a program and ignoring it? I've tried using the terminate handler (vector 0x0102) but that gets control on *any* type of program exit (ie, even if you called exit()). I can't find anything in the atari docs that says how to tell if the terminate handler was invoked by a detection of ^C in DOS, but (oddly enough) they call that vector the ^C handler in the docs.

(Actually, leave out the "and ignoring it" part of that question. I can handle that part of it with a longjmp, I just need to be sure it's a ^C termination and not a normal program exit.)

(Also, suggestions like "uninstall your 0x0102 handler in the exit() routine" are Not An Option for me -- the program could have done a Pterm() or a gemdos(0) or something else that I can't catch at all.)

|>

What a quote... :-)

A simple question: Is the computer connected to ground/earth?

I've had the same problem on two systems.
The first was an Aquarius computer which wasn't able to read
data casettes with a casette recorder. After I discovered that reading
succeeded when the TV (monitor) was switched off, I made the computer
connected to the ground. It worked, the computer was even capable of
reading bad casette tapes from other persons, that it wasn't able to
read before.

The second one is my Atari ST I'm using now. The harddisk gave trouble,
and after I connected all metal cases and the ground of the power supplies
to the gound/earth there was no problem anymore. The same applies to
a friend's ST (another configuration). I believe that computers
and especially the high-frequency connections are very
sensitive for radio interference and magnetic fields.

Maybe you can give it a try..... I hope it works.

Greetings from Holland,

Joost van Surksum

P.S. It's no use replying by email, I finished my training period
over here. I leave today. If you want to reply, please use this

Very strange! I cannot see any logical reason why different language versions
could be responsible for this bug. I am going to ask the guys from BELA at
Atari fair next week about it.

Still wondering,
Markus.

According to the official documentation, you are not allowed to to further GEMDOS calls from within the terminate handler. This means, that all current 'solutions' that *do* catch CTRL-C this way are doing something unofficial (note that it's easy when you are using MiNT...).

> (Also, suggestions like "uninstall your 0x0102 handler in the exit() routine" are Not An Option for me -- the program could have done a Pterm() or a gemdos(0) or something else that I can't catch at all.)

The terminate handler is called *BY* the Pterm*() functions -- you can rely on that to remove your handler.

> What's a good method of trapping a ^C from within a program and ignoring
> it?

Psignal(SIGINT, SIG_IGN)...

...oops; you're not using MiNT? Well, then it gets a lot harder :-).

Actually, I'm afraid there isn't any very good way to catch ^C in the general case. If you use the terminate handler, not only do you have to worry about Pterm0() and similar kinds of exits, but you also have to watch out for Pexec() (i.e. the program terminating may not be the one that you want to prevent from terminating).

The "best" way to do this under TOS, I think, is to not allow ^C to terminate programs at all -- do all I/O in raw mode (e.g. through the BIOS) and look for ^C's yourself. That's what we did in the original gcc library.

Next best is to require people to exit using exit() and unhook the 0x0102 vector there; also, in execv() unhook the vector before running a new program. You said this wasn't an option, but perhaps you could make it an option by specifying this in the docs for your library.

Last best (IMO) is to catch trap #1 and look for Pterm() calls, as well as hooking into the 0x0102 terminate vector. This may cause problems under MultiTOS or MiNT, though, if other programs are running at the same time.

3169. my floppy drive lies to me: a cry for help...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-14 20:10:00 UTC
From: ugafence@ubvmsb.cc.buffalo.edu
Message-ID: <BszMKn.B8K@acsu.buffalo.edu>
Source record: 43267

Help.

I seem to have come across a (as far as I know) strange problem. My internal floppy drive on my Mega is working perfectly (rpm, dma read, etc.) except for the fact that it won't write or delete files. If I try to delete something, it does the job and the directory window updates appropriately; BUT, if I take the disk out and reinsert it, it shows the file as still being present, and unchanged. Nor can I create files.

I presume the generic verdict is that the drive is dying. But perhaps somebody has some personal experience or some recommendations of things I could try. I'm not adverse to removing the drive and tweaking.

If you can offer any assistance, thank you..

.Philip

ps - I did recently install the TOS switch as per the guidelines received with TOS 2.06. I don't believe this to be relevant, but you never know.

3170. Opening aux1

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-15 02:15:12 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Aug15.021512.11496@csi.uottawa.ca>
Source record: 43268

Here's a possibly dumb question:

How do I open a file to aux (a.k.a. modem1, a.k.a. com1: ...)?

I've compiled C-Kermit, with only minor difficulties, and it seems to work, up to the point at which I try to actually USE it to do file transmissions.

It requests that I "set line", which is sensible enough.

If I'm running MiNT, I enter /dev/aux or /dev/modem1. It complains about being unable to acquire a "lock" on the device, but life continues. Unfortunately, data doesn't get transmitted.

If I'm NOT running MiNT, there's no sensible way to actually NAME the device. In the good 'ol 8 bit days, you could ALWAYS open a file to ANY device, whether that be D1:, D2:, for disk drives, or E: for the "line editor" device. On MS-DOS machines, file names like lpt1: or com1: get interpreted as devices; I don't seem to be able to do this from either tcsh or mupfel (or from inside C-Kermit). Do I need to hack up the code in order to get this running? Or am I missing the "magic name?"

Source record: 43269

I've been experimenting with some of the CLIs that are available for the ST/TT, and now I have a little question someone here could probably help me with:

What exactly is the difference between the commands 'set' and 'setenv'? I know what a variable is, and also what an environment variable is. I'm asking because the shell I have almost decided upon (Tomshell), doesn't have a 'setenv' (just 'set'). Other shells, notably gulam, have both 'set' and 'setenv'.

Does the lack of a setenv command in Tomshell mean it simply cannot set environment variables at all?

Bill Nell,
what is your address anyway? bnell@siemens.com bounces back.
(this happened what i tried to reply to this message yesterday, and
had happened in the past, maybe a mont ago when you asked about the
startup files)

to answer your question, gcc .o's are in unix a.out format. the
details of the format may be found in utilsrc/gnu-out.h, the
symbol table stuff in <stab.h> and <stab.def>, and a paper that may
help to (if you are not familiar with a.out) in
documentation/aout.ms.

cheers,

What's wrong with ACC's? I don't think they're such a bad idea.
I have to use Windows at work where getting hold of an
accessory is sumetimes quite tricky, for a start you have to remember
where it is (i.e which windowsetc) and once you do
remember where the ACC is you have to perform about 6 clicks to
get it before you can even run it.

I would suspect that you'd have to rewrite dLibs, Ian. The GEMDOS
functions Cconrs, Cnecin, etc. will terminate the program if they see a
^C. The output functions should be fixable without conversions, but not
the inputs. Of course, I could be wrong, but I had that problem myself
for quite a while. I finally reverted to using BIOS functions...

> Under MiNT... Psignal(SIGINT, SIG_IGN)

Yeah ::sigh:: unfortunately what I'm doing is trying to build a signal()
system for dlibs, for folks not running under MiNT.

> have execv() remore the 0x0102 vector

Aw sh*t you're kidding! I hadn't checked it, I just assumed GEMDOS would
be bright enough to manage the pterm vector on a per-process basis.

Actually, I had about given up on implementing SIGINT at all, but I was
gonna implement the ANSI-defined SIGTERM and tie it to the termination
vector. I was also going to use the termination vector to clean up hooks
in other vectors (for handling SIGSEGV and stuff). It looks like this is
gonna get to be more comlex than I had ever imagined. No wonder the
original dlibs didn't have a signal() system in it.

Well, I tested this on my TT, and the bug showed up.
BUT in st-high-res it didn't show up, so probably it'll work
in TT high as well. Unfortunately I don't have a high-res monitor.
My guess is that Eric is using a TTM194 and thus haven't discovered
the bug (yet)...

Although I agree in priciple, there is still the fact that there are many people who either can't use MiNT (lack of sufficient memory, etc.) or just don't want to all the time (sorry to say it Eric, but there still are bugs). For example, I don't use MiNT regularly because I don't have a hard drive yet. So, I live with .ACC's and TSR's. And I want programs I develop to be usable by most people, so I have to write .ACC's and TSR's.

Under TOS, it's called "AUX:" (that name also works under MiNT).
Unfortunately, TOS's Fwrite and Fread system calls are seriously warped,
so using AUX: to do anything useful can be tricky.

Hello,

I got a copy of Neodesk3 this weeken for a good price and it looks pretty interesting. However one big problem for me is i cannot seem to get it to work with MiNT.

Has anyone successfuly installed mint and have NeoDesk3 up and running?

Many thanks,

Scott Kolodzieski

>Does the lack of a setenv command in Tomshell mean it simply cannot set
>environment variables at all?

Perhaps it follows the sh/bash/ksh convention, where variables can be
"set" (actually, no keyword is used, just "VAR=value"), where variables
may be tagged as "for export", using "export VAR". The difference is that
variables that are not exported will not be passed down to child processes,
so if, say, you set FOO=bar, but do not export it from your shell, a subprogram
would not receive the "FOO" variable.

(But I have never used Tomshell)

3187. Interrupt interference

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-17 05:01:25 UTC
From: sourada@iastate.edu
Message-ID: <sourada.714027685@vincent1.iastate.edu>
Source record: 43286

I'm writing a routine to hang off the 50Hz interrupt. This routine often takes as much as 2 ms (long, yes, but unavoidable). The problem is, this seems to interfere pretty badly with timing-intensive things like serial and disk access.

I've tried the few things I could think of to alleviate this problem: flock is checked at the entrance to the routine, if it indicates the disk is in use, the routine is exited immediately. If not, the IPL is lowered to 3 to allow other interrupts and work proceeds.

This, apparently, is not enough. Most of the time, disk accesses don't cause problems, although this does happen sometimes. Serial port access seems to bomb fairly frequently, even at lowly 2400 bps.

Finally, the obvious question: What can I do to ensure that my routine gets the time it needs without bringing down the whole system? Is there a uniform way to see if some time-critical operations are going on? Is there a way to allow these to go on without my routine interfering too badly?

3188. Re: Continuing 1.44 Drive Woes

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-17 07:39:32 UTC
From: reeuwijk@dutentb.et.tudelft.nl
Message-ID: <1992Aug17.073932.15272@donau.et.tudelft.nl>
Source record: 43289

I got this from the Atari Benelux BBS:

Technical information date: 25 may 1992 number: 105

High Density drive in MEGA STE

If you install a high density kit in a MEGA STE with a serial number starting with A13 or a lower number (for example: A09) and it doesn't work in HD mode then the following points must be checked:

Test if there is a connection between U7 pin 32 and UA2 pin 19. If there is no connection, solder a wire between these points.

Check if the PAL UA2 has the CO number C301901-002 (the PAL C301901-001 doesn't work with a HD drive). C301901-002 has order number 620100 [for Atari Benelux at least - CvR].

Disclaimer: I only translated this. I'm not responsible for fried Ataris or HD drives.

Remember that you may need a AJAX chip to replace the original disk controller. I recommend the replacement anyway since even if the original controller works at the higher speed, it was never designed for it.

Since I am one of the unlucky victims, I will try the patch above as soon as possible.

3190. Using Setexec() [a bit of help needed]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-17 08:30:05 UTC
From: ssw@aber.ac.uk
Message-ID: <1992Aug17.083005.6390@aber.ac.uk>
Source record: 43288

Greetings,
I am currently writing a little program in C which requires that
certain errors, notably bus and address errors should be trapped. According to
my copy of ``Internals'', Setexec() (BIOS function 5) will do just that and is
defined thus : long Setexec(exec_no, vector)
int exec_no ;
long vector ;

Where vector is the address of the routine to be executed when a certain error
occurs, and exec_no is the execution number.

My program is (roughly) of the following form :

```
main(argc,argv)
int argc ;
char **argv;
{
:
assorted code
:
}

BusError() /* This should be executed when a bus-error occurs */
{
printf("Bus Error!\n") ;
}

AddressError() /* This should be executed when an address error occurs */
{
printf("Address Error!\n") ;
}
```

The question is, what do I pass to Setexec() for the addresses of each of these
functions? According to my book on C, just taking the address of a function is
not allowed.....

Help would be greatly appreciated.

Thanx in advance,

Simon.

3194. 520 ST problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-17 15:08:58 UTC
From: jeffh@oakhill.sps.mot.com
Message-ID: <1992Aug17.150858.5603@oakhill.sps.mot.com>
Source record: 43098

Over the weekend, I picked up a 520 ST. When I turn it on, the screen flashes white for a fraction of a second, then goes black. The computer doesn't seem to be looking at the drive (looking for a boot disk), so I assume TOS exists in ROM (this is my first experience with an ST.) Shouldn't I get some sort of display here? I opened the case and checked all the voltages. Everything checks out. I noticed a bunch of empty sockets off to the right. There were 2 ROM (?) chips installed, but I suspect there may be more necessary (?)

Thanks,
Jeff

yes, you need to pop off the exeception frame. also remeber
that different members of the 68k family have different exception frame
formats. (you can test the word at location 0x59e on the atari to test
for the presence of a non-68000).

Your book is (unfortunately) wrong. The following code should compile and
execute under any C compiler. The name of a function evaluates to the
address of the function just like the name of an array does.

```
#include <stdio.h>
main()
{
void (*jumpto)(); /* A pointer to a function. */
void sec_on(); /* Declare that the sec_on function exists. */

jumpto = sec_on; /* Set the pointer to the address of the function*/
jumpto(); /* Execute the function that's at the address
* pointed to by the pointer.
*/
return(0);
}

void static sec_on() /* this is the silly little function */
{
printf(" this is sec_on()\n");
}
```

This is standard C stuff. Another good source of help with C is the group
comp.lang.c. It is full of people who don't know GEM or TOS, but can answer
C questions.

This sounds amazingly like an Atari-sized version of the Tandem T16 NonStop architecture that has taken Tandem Computers to a dominant position in fault tolerant computers and transaction processing. This would NOT be a trivial development effort, but WOULD result in a potentially killer machine. It would NOT fall into the price range wherein Atari has traditionally been reasonably successful. I would certainly like to see it happen. So who's going to tell Sam T.?

>This is an utterly bizarre idea that will either send you into a
>screaming fit or drop your diastolic blood pressure ten or twenty
[idea of making a 68k based multiprocessor Atari machine removed]

This sounds like a good idea, except:

1) The 68ks were not built for multiprocessing (big surprise) - you are not only talking about totally (almost) re-writing TOS to handle the multiple processors (which sounds like a good idea to me anyway), but you would have to implement some impressive glue-logic to get the multiple processors to work cooperatively since they a) don't know that they don't own the bus, b) don't understand any kind of memory but super/user, c) only have 24bits address line (and you really want to be able to share some of the memory so you can at least pass information between processes/virtual machines).

2) Related to the last point of 1), you really want to have a distributed multiprocessor-system - how many times do you run 27 applications simul-taneously? Not to mention that each processor would have to have its own memory - and it doesn't sound too appealing or marketable to have to buy 27MB so you can have 27 1-MB virtual machines. That and the fact that each would still be going at the original (single processor) speed. By having a distributed multiprocessor system, you distribute tasks over the multiple processors so that you can have (with properly written software) a (several) programs executing in parallel over as many processors as is possible/feasable. Therefore, you get a faster execution time with a slower (=cheaper) technology.

My suggestions:

To address 1) above, use a 68040 as a minimum - you need not get a faster one, (<=25MHz should be more than enough, and with the '040/33, prices should be dropping) - this would be an excellent choice of multiprocessor as it has built in cache w/cache snoop (if something on the bus requests data that is cached on the '040, it supplies the data), MMU so that memory can be partitioned however needed (ie. processor N's memory, sharable, etc.), and it can address 32bits of dataspace so that a huge chunk of memory can be partitioned dynamically to the processors. Most importantly, the '040 does not bus-master the bus - it requests access to the bus just like any other device on the bus, thus making it nice for other processors that might be present.

So how does that sound? Atari - feel like making some low-cost multi-processor workstations?

-Mike

> running and switching between 27 processes, executing no more than one
> instruction at a time (for roughly the same amount of money)?
Two problems:
- (1/2) stuff that much electronics in a little box
- (1/2) supply enough electricity without melting the box
- (1) let 27 microprocessors access the main memory
simultaneously

(the first two are marked 1/2 because the can be easily fixed: ;-)
- get a bigger box
- get a better power supply

There also is a simple rule:
The more chips, the more bucks!

It's not only the chips that make this, but the mainboard design.
You need local memory, cache, or something else.

> the IPL is lowered to 3 to allow other interupts...

It may take more than that. The interupts are also prioritized within
the 68901 MFP chip. If MFP autovector interupt 12 is running, for example,
then any interupts coming in on vectors 0-11 will be left pending until the
ISR for vector 12 clears the inservice bit. I don't have my MFP docs handy,
so I'm not sure this affects you -- I vaguely remember that the 200hz timer
is pretty low in the MFP priority list.

3202. Re: Using Setexec() [a bit of help needed]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-18 00:27:02 UTC
From: ilepore@nyx.cs.du.edu
Message-ID: <1992Aug18.002702.7663@mnemosyne.cs.du.edu>
Source record: 43047

Organization: Nyx, Public Access Unix at U. of Denver Math/CS dept.
X-Disclaimer: Nyx is a public access Unix system run by the University
of Denver for the Denver community. The University has neither
control over nor responsibility for the opinions of users.

Using your example code, your call to set the interupt s/b:

Setexc(2, BusError);

But, since BusError() appears later in the code, you'll also need to add
an "extern void BusError();" before the Setexc() call, or move the BusError()
routine earlier in your code. That handles the C-syntax part of your
question, but the full answer is longer...

Depending on your compiler (you didn't say which one you're using), you
may need to declare BusError() using a keyword such as _interupt. If your
compiler doesn't support that keyword, there's a good chance you won't be
able to write the BusError() routine in C. When the routine gets control,
the machine will be in supervisor mode. Trying to use printf() in supervisor
mode will probably lead to a crash.

The best fix is to use signal(SIGSEGV, handler_function) if your library
includes a signal-handling system. If it doesn't, here's some assembler
code which you should be able to adapt to your purposes:

```
---------- cut here ----------------
;************************************************************************
;*
;* EXHANDLR.S - Machine exception handler.
;*
;* This module hooks exception vectors 2, 3, 4, 5, 8, and 102 to catch ^C,
;* null pointer de-referencing, and so on. When an exception occurs, the
;* handler routine cleans the exception info off the supervisor stack,
;* forces the machine back to user mode, and does a longjmp() through
;* the jump buffer specified during the init call.
;*
;* This code can be assembled with MadMac or Sozobon's JAS.
;*
;* Typical usage is:
;*
;* RESTART_PROGRAM:
;*
;* if (0 != (exception = setjmp(exception_handler))) {
;* exh_remove_handler(); /* prevent ugly recursions */
;* if (exception > 0)
;* printf("Exception %d has been handled.\n", exception);
```

```
;* else
;* printf("Process termination has been handled.\n");
;* goto RESTART_PROGRAM; /* or exit() or Pterm() here */
;* }
;* exh_init_handler(exception_handler);
;*
;* The salient points are to install the setjmp() before the init_handler
;* call, and to be sure and remove the handler as the first thing right
;* after a return from longjump, to prevent recursion if another exception
;* happens while you're handling the first exception. If you are going
;* to take some restart action instead of terminating the program during
;* exception handling, be sure to re-install the setjmp() and the
;* exception handler before getting into your main logic again.
;*
;* Remember that the processor termination handler catches ALL
;* terminations, not just ^C, so if your program has exit() calls all
;* over the place, plan to get control if one of them is used to exit
;* the program. As of now, I don't know of a good way of catching only
;* ^C terminations but not exit() terminations. (Other than replacing
;* your library exit() routine with something that removes the handlers
;* and then continues by calling _exit(). Not all libraries support a
;* two-tiered exit/_exit system, dLibs does.)

I AM using MiNT and it is fine, but as long as there is no MultiTOS available
I _have_ to use ACCs in order to get a sensible Window-System with terminals.
BTW even Eric Smith uses TOSWIN._ACC_ to use terminal sessions and GEM-
applications at the same time. I know, MultiTOS is "comming soon"*, but
who knows about the quality of the implementation of Multi-AES ??

cheers,
Martin Gergeleit <mfg@gmd.de>

*"comming soon" is a trademark of ATARI

>
> Has anyone successfuly installed mint and have NeoDesk3 up and running?
>

Hi Scott,

this is an old problem: NeoDesk refuses to start if MiNT is active.
Having MiNT 0.94 installed, you could start Neodesk in the following way:
- start MiNT in the Auto folder
- start GEM from MINT.CNF (last line = #INIT=)
- start mintshel as an AUTO application
- start Neodesk from mintshel.rc by the last lines:
cd $NEODESK # here lives Neodesk
neodesk.exe # not neoload.prg !!!

But this does not work with MiNT 0.95 !!!
You have to initialize MiNT, GEM, your environment (by mintshel) and then return
to the normal desktop. Now you will be able to start Neodesk as application.

Strange, but this method forks fine for me...

BTW: I am thinking of replacing Neodesk by GEMINI if no new Neodesk version
is launched on the atari fair in Duesseldorf as last year...

If jumpto is a pointer to a function, won't the call jumpto() cause a "bad
indirection" error in the compiler? Shouldn't it be called by
(*jumpto)(); ?

Just nit-picking, but it will only work with ANSI C compilers (as
opposed to `any' C compiler). For K&R C, you'd have to write

```
(*jumpto)();
```

Furthermore, to make the thing bullet-proof, you could declare jumpto as

```
void (*jumpto) (void);
```

>This is standard C stuff.

Yes, but not every C compiler understands standard (= ANSI) C. As I
said before, I was just nit-picking, and this is not a flame.

Have fun.

=>
Nope ... this works perfectly on my C compiler (Sozobon V2.0) ... you've just got to be careful to declare the functions appropriately. Thanks to those who helped me suss this out BTW -- error trapping has never been so much fun :-)

One side note, to the person who suggested I post this query to comp.lang.c, I didn't for two reasons :

- This is an Atari related problem (now sorted out)
- The people in comp.lang.c seem too busy flaming each other about coding styles.

Simon.

PS. Anyone know of a decent reference book for Atari programming? I've discovered (the hard way) that ``Internals'' is a load of crap :-(Preferably, the book should have a little in it about STe specific bits and something about the TT would be nice too.

Thanks in advance.

3210. format of object files in gcc

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-18 17:40:59 UTC
From: <>
Message-ID: <bnell.714159659@ferrari>
Source record: 43064

Can anyone tell me where to find the format of the .o files used by gcc? I don't feel like wading through the source or anything like that. I would prefer some simple docs. I want to write a program to convert them to DRI or GST format so I can link them with object files from my assembler (and yes I know gcc can do inline asm but I hate the syntax). Also, I guess I should ask if anyone has already made such a program already to save myself the trouble.

Thanks,
Bill

>Here it is in a nutshell: a parallel processing Atari microcomputer
>featuring a set of 68000 microprocessors, sold at low cost yet
>featuring high technology.

In 1985 or so, a company called Alliant Computer Systems based in Littleton, Massachusetts, introduced their FX series of machines, with the FX/8 being the main product, 8 68020-clones in a single chassis. This mini-supercomputer was outfitted with special vector-processor hardware as well, and cost around a million bucks. Alliant went bankrupt this year, and FX/8s now cost around $30K or so second-hand.

It's an interesting idea, but it takes hard work to get it right. Alliant abandoned the Motorola family in favor of the Intel i860, (which I think was a mistake) but their operating system was a pretty mature product already.
> * * *

>As I glanced at my JDR Microdevices catalog, I couldn't help but wonder

>size having to make the single microprocessor do more and more things
>faster and faster?

Sure is. But still, it's very difficult to break up a problem into segments that can be run concurrently. If you can't partition your problem this way, then parallel multiprocessing doesn't gain you anything.
>
>The catalog I referred to lists the price of microprocessors you can

>costs $189.95. The IBM PC's Intel 8086 costs $5.95 while the 80486
>that runs at 50 MHZ costs $1199.00.

Hm. The cost is certainly attractive, but I still wouldn't want to use anything less than a 68020 in a system I were to design today. A real 32 bit architecture, instead of the 16 bit data/24 bit addressing of the 68000, plus the support needed for virtual memory, exotic address spaces, etc. Just can't see developing a Real Computing System without it.
>
>Let's see: $189.95 / $6.95 is about 27, and $1199.00 / $5.95 is about

>instruction at a time (for roughly the same amount of money)?

If you had 27 things you wanted to do right away, all at once, this would
be fantastic. In my day to day use, I seldom have more than 4 windows open
on my X terminal, and I'm generally only actively using one or two of them.
When I ftp a new distribution of the X window system, or GCC, or some other
large package, I actually do compile them in parallel on our FX/8 or FX/800,
using up to processors at once on the 8. It's wonderful. But it's not a
common occurrence. (See my paper "GNU & You, Building a Better World" in
the proceedings of the 9th Annual Sun User Group conference...)
>
>For that matter, couldn't you do more with 201 good 8086's running
>exactly one process each, in parallel, than you could with one 80486
>running 201 processes all at once (for roughly the same amount of
>money)?

For roughly the same amount of money, you would have to scale back
severely from 201 processors. It takes a tremendous amount of logic to
synchronize a bus between a large number of processors.
>
>Consider what a great product Atari could have, flying into the twenty-
>first century at low cost, if they could write an operating system that
>is based upon the architecture of one microprocessor for each process
>that can run. It wouldn't be that hard, if my thinking is correct:
>each process runs on its own microprocessor with its own memory,
>totally protected, so as to achieve instances of deaf, blind, and mute
>minicomputers all inside the same box. (These computers inside of
>computers will be referred to as DBMT's: Deaf, Blind, and Mute aTari's.)

This is called asymmetric multi-processing. Sun is taking this approach in
Solaris 1.x, and going for symmetric multiprocessing in Solaris 2.0. The
Alliant Concentrix operating system was fully symmetric. It's just fine to
have one processor per Unix process, but if you have only one kernel "process,"
then you get serious performance bottlenecks. 27 or 201 processors making
system calls to a single OS process will be a major drag. You will find most
of your processors waiting in spin loops for the OS processor to complete
their service requests.
>
>The operating system would only wait for system calls to be issued from
>the various DBMT's and then handle the requests.
>
>Each DBMT would be constructed on a single plug-in board and there
>would be as many of them as you had slots to plug them into. (This is
>beginning to take on mainframe proportions!)

That's a good idea. I think Alliant painted themselves into a corner by
only allowing a small fixed number of processors per system. (8 procs on
an FX/80, up to 28 on an FX/2800.) Like the transputer approach, where there
is no predetermined limit to the number of processors you can connect. But

again, the control circuitry for this approach gets quite complex.
>
>The process that desired to run a program would issue a system call,
>and could either wait or not for it to finish. The operating system
>would start the next idle DBMT. Disk access and window graphics would
>also be system calls, giving good separation from the operating system,
>and excellent protection (no more crashes either). Actually, the
>protection would be perfect, leaving no possibilities whatsoever for
>the user to tinker with system globals, keyboard vector interrupts,
>vertical blanking interrupt routines, etc.

So you're implying absolutely no sharing of memory between processor nodes, eh?
That means all communication between a node and the OS processor has to be by
DMA transfer? That will also introduce a performance hit. Motorola's DMA
controllers only operate at speeds of up to around 10 or 12 MHz, for transfer
rates of about 4 or 5 MB/sec. That's not so terrible for older SCSI-1 block
devices, but that imposes tremendous overhead for tty-style character-at-a-time
I/O processing.
>
>Perhaps this parallel concept would be applied to the filesystem as
>well. Don't wait for a single head to reposition itself over and
>over again while the programs are twiddling their thumbs -- use several
>small drives or some such scheme to prevent the tremendous speed of

>DBMT with message passing between them through the operating system
>would speed up any program. So Atari could make the most effective
>microcomputer on the market today. Atari would supply the buyer with
>tools to write parallel-processing programs in ordinary languages
>to get things rolling.

This is a very hard problem. To be able to easily split a single program
among different processors, you really want to have shared memory between
those processors, which is something we've already excluded from this design.
Aside from that, it takes a different mind-set to get out of writing programs
in the start -> crunch -> stop model of linear computing. Current compiler
technology just takes traditional code and tries to run loops in parallel.
If you have a huge processing job but it just consists of a sequence of steps
that run in series, you can't get any benefit. (What you do then, of course,
is fire off multiple instances of the job on multiple processors... But if
you only need to run it once, you can't win.)
>

>Atari would have been one of the firsts to jump beyond the single
>microprocessor barrier for the average home computer, giving users
>fantastic power for the software that will soon arise that needs more
>than a single microprocessor can handle (even with a math coprocessor).
>
>Because each DBMT is just that, deaf, blind, and mute, it would not
>have to worry about I/O devices, leaving only the microprocessor and
>memory to be installed on each DBMT board. Such a modular design
>would be easier to construct and debug at the hardware level.

It's an interesting idea. Sounds much like a transputer network, but with
no internodal communications.
>
>It's about time that someone tries this out in one form or another
>for reasonably-priced small computers, and Atari could pull it off.
>If they did, it wouldn't be perfect, since no new ventures like this
>are, but they could start things rolling and place their name in
>history.

Actually, thinking about this a bit more, there's no reason to limit such
a design to any specific model of processor. Ok, so we have a single bus
master that's basically a request dispatcher. When "the system" is booted,
this guy starts up, inits the I/O subsystems, and inits each processor
module. The processor modules and I/O modules can be pretty interchangeable,
basically a card that resides at a particular bus address, with a processor,
memory, and if an I/O module, whatever I/O channels it requires.

Hm. With a 68020 or up as the central system, you can have up to 256
24-bit (i.e. 68000) nodes. (Assuming that you decode the function codes & such,
giving a full 32 bit address space for the 68020 itself, and another 32 bits
for the nodes... Maybe even more if you care to distinguish I/O nodes from
processor nodes.)

Ok, now, in order to make each single node useful, they need to have a good
amount of RAM. I guess 4M is good for most common tasks. But wouldn't it be
silly to have, say, 16 nodes == 64M of RAM in your system, but you can't run
a single program that wants 8M because your memory is in 4M chunks? I guess
this tells me that you've really got to have a single memory pool, with
shared access to all the processors.

Ah, this brings up another issue. So I can buy 27 68000s for the cost of one
68020. I probably can't afford to outfit all 27 of 'em with enough RAM for them
all to do reasonable work, eh? I think it should be obvious from all this that,
when you're designing a computer system, deciding on the processor is one of
the easiest steps. Creating the memory system is the hard part, everything
depends on its performance.

>baffoni@aludra.usc.edu (Juxtaposer) writes:
[my suggestions for minimum hardware on a multi-proccessor system deleted]
>Sounds like the new Falcon to me.

Not even. For starters, it has an '030 - no "other cache" awareness,
and still maintains bus mastership like the other Moto chips <'040. Although
it does have a Processor direct slot, it sounds like it is only 16bits wide
which would really blow chunks trying to put another proccessor on it. It
is (so far) limited to 14MB - not much room for concurrent processes, let
alone system space. And to top it off - there is not much room to spare
in that 1040STe style case - multiprocessors+glue are going to be big and
are probably going to generate a LOT of heat, not to mention likely to
totally waste the power supply.

However, this is not going to stop it from being an excellent
single proc. machine - very multi-media-ish.

3214. Detecting GDOS presence

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 00:56:21 UTC
From: hartlenk@newton.ccs.tuns.ca
Message-ID: <1992Aug19.005621.8575@newton.ccs.tuns.ca>
Source record: 43058

Lattice C v5.x provides a Lattice specific VDI function called vq_gdos() which returns 0 if GDOS is not loaded and non-zero if GDOS is loaded.

The description says "This function does not have an official name but uses an Atari approved method for determining the presence of GDOS." Anyone know what the "approved method" is so GDOS presence can be checked from Heat & Serve/Sozobon C?

Thanks in advance.

3215. More MiNT questions...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 03:39:55 UTC
From: torrance@ai.mit.edu
Message-ID: <TORRANCE.92Aug18233955@cookie-monster.ai.mit.edu>
Source record: 43061

Greetings, netters. I'm looking forward to getting a lot of mileage out of MiNT 0.95 with TOSWIN, but I've encountered a few snags.

First, it seems my system hangs whenever a program tries to ring the keyboard bell (^g in emacs). This happens from MiNTEmacs (from atari/mint on a.a.umich.edu), from Flash, and when using Emacs remotely within Flash. I have Tos 1.04, ICD Adspeed 16Mhz, and am running MiNT 0.95 with TOSWIN.

Second, when I try to use tip to get a terminal-in-a-TOSWIN window, it writes in the standard full-size system font to the bottom of the screen, scrolling my desktop out from under me until I exit with ~. . Messages from the tip program, such as [set?] and the ~h help appear where they should in a small font in the window. Have I failed to set something right? Is this (1990) version of tip the right thing to use?

Finally, I'd like to find a way to have some environment variables set before I start a new process under TOSWIN. In particular, I'd love to run Emacs in a TOSWIN window, so I can use the new TOSWIN emacs menu, but emacs can't find its lisp directories, etc. until I set my environment. Is there another place I can set this, or another solution?

Thanks for all your help,

3216. Slow hard disk with Spectre GCR :(

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 04:27:55 UTC
From: dtarico@violet.ccit.arizona.edu
Message-ID: <1992Aug18.212755.1@violet.ccit.arizona.edu>
Source record: 43065
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have recently set up a Spectre GCR on my system which consists of Mega 4 ST, ICD AdSCSI host, Maxtor LXT-200 disk drive. Also, I have Spectre v. 3.0, with a 50 meg partition formatted for Mac. The hard disk writes seem to be slower than they should be. It works ok, and reads seem sufficiently fast, but writes of large files seem slow.
For example, copying Superpaint 2.1 from a Mac floppy to the hard drive on my system took 1 minute 14 seconds. The same operation on a real Mac SE/30 took only about 23 seconds. On my system, during the write to the hard disk, it would pause so long that the light on the floppy would actually go out while it was waiting for a part of the HD write to finish.
Is this normal, and if so, why?? Thanks!

3218. ATARI 1040ST died: power supply question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 07:35:17 UTC
From: ca@informatik.uni-kiel.dbp.de
Message-ID: <10671@idefix.informatik.uni-kiel.dbp.de>
Source record: 43059
Cross-posted to: comp.sys.atari.st.tech,sci.electronics

A few days ago I got an ATARI 1040ST for free. Unfortunately it died yesterday.
My first guess was a failure of the power supply, since neither the floppy disk
drive starts nor the LED flashes. After opening up the case, I found a power
supply made by 'TAIWAN LITON', 'MODEL NO: PE-2350-2'. One IC
(labeled GE, H11AV, 1A, 8836) misses pin no. 6. Now my question: is this
correct ? Or could this happened during transportation ?
Are there any other things I should check ?

Thanks in advance,

Claus
PS: Please answer by email, since I don't read this group.

From: pjc@jet.uk
Message-ID: <1992Aug19.091600.29603@jet.uk>
Source record: 43063

The title says it all. I have a v32bis modem and an old tos1.0 ST.
Which cts/rts patch program is best used with this pairing. Am I
correct in thinking that the ST cannot run its rs232 port above 9600
baud under any circumstances?

Is hardware flow control properly implemented on the Falcon, I wonder?

From the specs of the Falcon which have just been published in
Brittish magazines I understand the thing will have a SCSI 2 port.
As I understand it it should be possible to hack a current DMA
port Atari hard drive so it fits in this but does anyone know for sure ?
Might there also be trouble with the current hard disk drivers ?

yes no wonder, the 50 Hz interrupt is level 6 (MFP)... if you run
there for too long you sooner or later get receiver overruns on serial
ports and other nasty things. (even atari themselves didn't get that
right: try reading a midi dump whild moving the mouse... :-(:-(btw,
does anyone know if `multitos' has that fixed?)

>badly?

well do you really _need_ the high priority? i mean would something
seriously break if the routine wouldn't be executed exactly every 20ms?
if not the solution is simple: use MiNT and make the thing a daemon...
(timing with usleep()/select() and maybe clock().)

otherwise you probably need a real-time OS... :-(

3223. Ajax chip upgrade

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 14:51:12 UTC
From: hartlenk@newton.ccs.tuns.ca
Message-ID: <1992Aug19.145112.2596@newton.ccs.tuns.ca>
Source record: 43068

I'm posting the following message for George Seto:

------------------------------ cut here --------------------------------

Does anyone know what sort of mods are going to be needed to get the
Ajax chips to work with a 520 or 1040 upgraded to the TOS 2.06?

Seems to me it's not just a simple plug in the Ajax to replace the
1772 and replace the 720K drive with a 1.44M mechanism.

Any ideas on what's needed for this upgrade? Thanks in advance....

Please post (email if you want), so that it can be saved for the FAQ

BTW for that FAQ, I have one thing.....

If you want to BOOT from drive B, just set memory location $446 to the
number 1. It is normally a 0 for drive A. This location does NOT get
wiped with a push of the RESET button. This was picked up from an old
UK magazine circa 1989. Don't remember whether it was ST User or ST World.

Sorry, but I don't think that will work. I was hacking around at one time on the MiNT kernel and attempting something similar. I hooked into the keyboard vector, trying to delete ^C from the keyboard buffer before Cconws(), etc. could detect it. Although I never disassembled the BIOS to verify this, it appears that the ^C often never gets into the keyboard buffer. I suspect that the keyboard interrupt handler takes action on the ^C as soon as it comes in (this must be flagged to occur only when higher level I/O routines are active...). Perhaps I screwed up in my code somewhere, but I could never find a ^C anywhere in the buffer.

|> My method is superior, simply because I get the sprite.SaveUnder almost
|> for free: YOU ALREADY HAVE TO READ THE SCREEN IN ORDER TO DRAW THE SPRITE,
|> so you may as well store that read data as you draw, saves reading twice.
```

Maybe, maybe not - it depends on your sprite drawing method. The code I originally
posted only read the screen implicity with
or.w d0,(a0)+
type instructions. Now if you do it explicity you need an extra 4cy (canceling out any
saving combining your save under code) and you need and an extra reg

which could slow down the rest of your code.

BTW the code I posted is (slightly) faster than the 32x32 sprite code in
your GNUchess port even under the most pessimistic assumptions (you did a great
job on the port though...).

|> Which reminds me - was this a competition? I wrote some VERY fast
|> sprite routines in a furious discussion with Dave B. - 60 or so
|> single-bitplane 16x16 sprites at arbitrary positions on an arbitrary
|> background was I believe my limit...

No, it was just a sugestion for a better competition goal than the rather
pointless TOS hacking in Nat!'s competion.
60 sprites at 50Hz is quite amazing on a non-blitter ST. At 25Hz rather less so.
Still I can't resist the challenge...

Steven

move.w d0,(a1) ; replace
addq.w #8,a1 ; next word
swap d0 ; low part of mask
and.w (a1),d0 ; combine with bgnd
swap d1 ; low part of sprite
or.w d1,d0 ; combine
move.w d0,(a1) ; replace
```

Come to think of it, if the sprites are only one pixel deep why not preshift the blighters???

3226. How to detect imminent DA activation ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 18:32:09 UTC
From: eker@loria.crin.fr
Message-ID: <447@muller.loria.fr>
Source record: 43071

Is there a clean way of detecting that a DA is about to become active so that I can replace vectors and clean up any other mess that might cause incompatibility?

Also is there a reliable way of knowing when the DA has become inactive and its safe to grab the vectors back (I know I could wait for th inevitable redraw messages but this seems hacky).

I ask because my application (a sequencer) needs to steal a number of vectors (incl MIDI/IKBD, timerA) that the DA (maybe another MIDI prog) might also want.

Steven

3227. How to hook into GEM?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-19 18:39:35 UTC
From: eker@loria.crin.fr
Message-ID: <448@muller.loria.fr>
Source record: 43072

Suppose I write a snazzy motif-like GUI, how do I hook into GEM so that I can run GEM DAs from my snazzy 3D menu? More particularly

1. How do I find the full (menu entry) names of the available DAs?

2. How do I find the 8 char names for appl_find()?

3. Is it sufficient to just to send the DA a suitable message thru its pipe or does more need to be done to get it active?

TIA

Steven

3228. why does rsrc_load() always rev up the floppy drive?

Newsgroup: comp.sys.atari.st.tech

Hello, Atarians,
As a recent poster just described, I also have just gotten a possibly dead machine. A 520 ST and a single-sided drive, both with out power cables. Is there a source for these items? I don't want to spend too much money, because it's working condition is unknown, but it has a load of software that I want to check out. Thanks for your time/bandwith.
Email or post is fine.

I don't know about anyone else, but I have an old 1040ST with v1.0 roms,
and I have done file transfers at 19.2K with no problems whatsoever.
This was using one of the "rz" programs from a commandline.
It got decent CPS as well. (don't remember exactly, was a while ago.)

>baud under any circumstances?

Try serialfx up on atari.archive - that should fix it. All ataris can
get up to 19.2kbps, but if you are communicating with modem, you have to
have the CTS patched. I think there was some commercial software called
intercomm that supposedly worked at 38.4kbps without special hardware, but
I never got it to work (with a friend's Amiga) so I don't know if it really
works - but now that I think about it, I had tried it before I knew about
the RTS/CTS bug, so that may have been the problem...I'll have to check that
out sometime.

>
>Is hardware flow control properly implemented on the Falcon, I wonder?
>

Good question - Atari hasn't had such a good track record - only
3 of 10 work without patches (actually 2/8 as 2.XX and 3.XX are basically
the same).

Trying a different mech is my next step, since it always err's on track 45 while formatting any HD disk, this may be from a defect in the 'head rails'\ of the drive(?) Now to look for a place that sells these drives with the best price (or will any 1.44 drive work with correct jumpers?).

Which is definitely wrong!
Even for the simple 68000!
What do you think are the pins ~BR(bus request),
~BG (bus grant) and ~BGACK (bus grant acknowlege) for?

> b) don't understand any kind of memory but super/user,
They understand:
supervisor program
supervisor data
user program
user data
That can enhance the 16 MB limit (see below) to 64 MB,
but what does that do WRONG????

> c) only have 24bits address line
Which means 16 MegaByte and should be enough on a multiprocessor system
where you have, say 8 MB private an 8 MB shared RAM for each processor.
That's 27 * 8(private) + 8(shared) = 224 MB main memory. Not enough?
Boy, your last name is croesus isn't it?

> 2) Related to the last point of 1), you really want to have a distributed
> multiprocessor-system - how many times do you run 27 applications simul-
> taneously?
Why? you can split ONE application into several THREADS!

> Not to mention that each processor would have to have its own
> memory - and it doesn't sound too appealing or marketable to have to buy
> 27MB so you can have 27 1-MB virtual machines.
Make it upgradeble at least one and at most (as much as you want).
1MB is much for that task.
Even 8MB (shared) main memory and 128KB (private) cache may be enough
with a hardware supporting virtual memory.

> [...] a distributed multiprocessor system, you distribute tasks over the multiple
> would still be going at the original (single processor) speed.

There you address the one and only problem: THE SOFTWARE!
You need a distributed environment!
A parallel OS and parallel Applications which means
parallelising (? ;-) developement tools.

THAT'S THE REAL PROBLEM AT ALL!

At least with ATARI! ;-)

>I was told by many vendors in the UK that it was not possible.

>Please could the relavent people post their replies as I would
>love to be able to connect my RLL/MFM Priam 519 drive up.

1st: You will need to have a host adapter to translate the ST's ACSI into SCSI. Supra, ICD and others? are manufacturers of such a board. ICD seems to support the widest variety of hard disk mechanisms.

2nd: You will need to have a SCSI to RLL or SCSI to MFM controller. Omti and Adaptec were manufacturing these, but I don't know for sure if either of them made a controller to work with your drive. Omti at least is no longer manufacturing these and I don't know about adaptec. If you really are insistent on this you might want to contact ICD at (815) 968-8550 or fax them at (815) 968-6888 in the USA.

3rd: You will need a power supply and enclosure along with the necessary cabling.

Unless your drive is very large and very fast or you have some particular emotional attachment to it, you probably will be better off using a SCSI drive as it will be faster and cheaper to connect. You may find it very difficult to obtain the SCSI to RLL/MFM controller.

If the MIT 68000 syntax is the problem, I believe GCC has a compiler-time
option (ie. when making gcc) to support Motorola syntax. Personally, I
prefer MIT now anyway (probably because I never got into Motorola much).

>warwick@cs.uq.oz.au (Warwick Allison) writes:

>This is fine. but is a previous post you mentioned that sprites could
>be updated at different speeds which made me think you were using some
>arbitrary interleaving of draws & wipes.

Oops, poor qualification by me. Obviously, it is DAMNED HARD to give
arbitrary sprite priorities, AND arbitrary update rates. (Although
possible - using full-screen masks, which are also useful for clipping,
moving "behind" playfield objects, etc.) If I even need such Sprite
classes, I'll have my head examined.

>Maybe, maybe not - it depends on your sprite drawing method. The code
>I originally posted only read the screen implicity with
> or.w d0,(a0)+

Hardly useful for anything but UNMASKED single-bitplane graphics, which
is next-to-useless (at he very least, you usually want to have black
and white sprites (like the ST mouse pointer), rather than just black
sprites (like the Sun SunView mouse pointer)). Of course, in the
interests of competition, anything is "useful" :-).

>BTW the code I posted is (slightly) faster than the 32x32 sprite code in
>your GNUchess port even under the most pessimistic assumptions (you did a great
>job on the port though...).

<delight> if you can mail me code-for-code patches, I'll put them into
my library (which will be free-to-all one of these days).

>|> Which reminds me - was this a competition? I wrote some VERY fast
>|> sprite routines in a furious discussion with Dave B. - 60 or so

>No, it was just a sugestion for a better competition goal than the
>rather pointless TOS hacking in Nat!'s competion. 60 sprites at 50Hz
>is quite amazing on a non-blitter ST. At 25Hz rather less so.

Actually, I think it was more like 50 at 72Hz (ie. mono).

>Still I can't resist the challenge...

You didn't post performance stats! How well does it BURN?

Let's make some categories:

1. Preshifted / Unshifted
2. 16x16 / 32x32
3. Masked / Unmasked (ie. black&white / black)

>Come to think of it, if the sprites are only one pixel deep why not preshift
>the blighters???

Yep. One better: with unmasked sprite, why even HAVE sprite data?
it uses only 100% more RAM to have the sprite data be the CODE ITSELF,
ie. automatically generate the

orl #....,(a0) (3 words)
addl d0,a0 (1 word)

instructions from the 2-word sprite-data!

(Of course, this is only acceptable for HACK CONTESTS. Anyone who seriously
considers this a "programming technique" is a beauxault)

I've never tried to do this, but you'd have to hook into the trap #2
call, i think, and look for the menuregister call from the desk accessory.
The main problem is that appearantly Gem replaces it's own vector in
the trap #2 vector handler after certain calls, so you have to recheck it
and re-replace it. There was a text file from Charles Johnson that I seem
to remember described the process, but I don't have it. Maybe someone else
does. You'd only need to hang onto it until the accessorys had all
registered, I'd imagine. Also, you'd probably want to pass the menu
register on to the AES when your done so the accessories could receive the
messages you then send down the message pipe.
>
>3. Is it sufficient to just to send the DA a suitable message thru its pipe
>or does more need to be done to get it active?
>
Once you know the id and name, it should be possible to send acc_open
messages. Harlekin allows keyboard macros to send open messages, so it
should be possible, though of course Harlekin manages it's own protocals.

These tricks are probably likely to break on various versions of the
os as well.

Also I recieved this in reply to one of my suggestions. I assume th
author doesn't want his name know or he would have posted this himself.

From:??????@eos.ncsu.edu
To: boris@sys6626.bison.mb.ca
Subject: Continuing 1.44 Drive Woes
Date: Tue, 18 Aug 92 10:26:53 EDT

In order to use 2MB drives you will need:

1. A 2MB drive
2. The new floppy controller chip (not the 1774)
3. Dip switch 7 turned on (in the drive bay, near front of machine)
4. TOS 2.06 (or 3.06 if you have a TT030)
5. Space between your monitor and your floppy drive (a monitor stand
will
suffice) because of interference.
6. The removal of the central screw (near transformer) in power supply
to reduce monitor jaggies (this is not really necessary, but helps)

I have set up many systems for customers of Computer STudio (Asheville,
NC)
and have a MegaSTe myself with a HD upgrade.

Hope it helps.

The Warp 9 Control Panel (accessory) allows you to load any font you want (and it comes with a lot of them). I just received my Warp 9 the other day and happened to be playing with this last night. (Actually, the 3270 font looks nice :-) But since I just started using this package (used to use Turbo ST), I can't point out any caveats, etc..

Good luck.

Another possibility is to get NVDI. The GDOS integrated into NVDI
has a special feature, namely that the names of fonts in the
ASSIGN.SYS file may be preceded by an s, in which case the system
font is replaced with that GDOS font. NVDI comes with some
alternate fonts, and if you don't like any of them you can use
any GDOS font.

3248. How can I "redirect" VDI graphics?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-20 21:47:41 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1992Aug20.214741.191331@rrz.uni-koeln.de>
Source record: 43095

Hi all Atari technicians,

one or two months ago it was mentioned in some context that I
don't quite remember that one should not u the setscreen()
function (XBIOS 5) in GEM progams at a all, as well as other
tricks to direct the graphics generated by VDI calls to somewhere
else than the "real screen". There certainly are good reasons to
refrain from using such techniques, but then again, they can be
very handy and useful too. For example, it is possible to make
the VDI draw in a virtual screen of an (almost) arbitrary size,
and then one can e.g. display this masterpiece in a window with
scroll elements by blitting parts of the picture into the window.
There has been a demo program doing this in the c't mag, issue
jan. '91 if I'm not mistaken.
Anyway, my question is if such a redirection can be done in a
"clean" way. The only thing I can think of right now is writing a
GDOS screen driver for that purpose but that is not only much too
laborious for me to do, but it would also be unelegant as it
would mean to re-invent all those VDI functions that are already
there in the ROMs...

curiously waiting for replies,

Jan

> how do I get a pointer to the screen?

void *screen = (void *)Logbase();

That's all there is to it. Oh, you've got to #include <osbind.h>. The
pointer type doesn't have to be void*; char* or short* or whatever you
want will work fine. Details of accessing screen memory are semi-complex,
due to the interleaved bitplane pixel organization.

> detecting GDOS...works from HSC/Sozobon

There's a function for it in GemFast (v1.7 and up):

```
long vgd_detect(void);
```

If it returns non-zero, GDOS is present.

Source record: 43106

```
Gday,
I'm working on a project that involves making an expansion card
for a MEGA st, and I'm trying to write a small assembler program to
detect whether the card is installed in one of two possible addresses. I
know that the card works correctly, so the hardware is not a problem. I
would like to write a program that attempts to write to the io address
of the card, and if it finds the hardware the read cycle will terminate
correctly, otherwise a bus error will occur & a handler will notify the
program that the hardware is not present.

My problem is that I get an address error when I execute a RTE
from the exeception processing routine, ala here is portions of my code

BusErrFlag dc.b 1 * flag variable for exception routine

MAIN pea.l BusErrHandler * Bus error handler routine
move.w #2,-(sp) * bus error exception number
move.w #setexc,-(sp) * set exception routine
trap #1

{... miscellaneous code here...}

move.b #$00,$CF0001 * try to write to my hardware
( this should cause a bus error exception if no hardware )

{ .... rest of program }

* this is the exception processing routine
BusErrHandler move.b #$FF,BusErrFlag * set flag for Bus error
rte
*** this is where i get "address errors" when I try to execute a
RTE from the exeception handler.

My question is, do I need to do anything special in the execption
handler before i execute an RTE ??

Thanks
Kym

The Mac Quadra uses a 40, and I understood that everything has to be
rewritten to run on it. Doesn't the 40 have some very different ways of
doing things, and aren't some instructions just gone and others added?
Wouldn't that mean the 40 machine would be a "from-the-ground-up" kind of
thing like the quadra is supposed to be?

Just wondering.

Well, there is an evolution between the falcon and the ST isn,t it ?
so why would ATARI not make a complete evolution, and go to a real
class a microprossessor (68040);
you're right, some instructions are missing, but that's for the speed,
less instructions, more speed..
so the Falcon 040 will really open new horizons..

>so wait for the high technology, and buy the falcon 040 !

I don't think this is such a good idea, for several reasons.

First, not everyone needs a high-speed machine. You don't need more
than say an 8MHz 68k to do basic WP. Musicians all over the world seem to have
been quite happy with the slow ST for quite some time - and the falcon offers
more speed and certainly more features than any ST has had.

Second, not everyone could afford a higher-speed machine. The Falcon
offers a LOT of good features that make it more than just a ST replacement -its
more like getting a slightly slower TT but with special cards already installed
(ie sound, video, SCSI-2). Not to mention multi-TOS. And the Falcon is cheap - especially
when you consider that you won't have to buy another monitor to
make it run (but is recommended) unless all you have is a mono monitor.

Third, Atari has put a lot of money into producing and developing this
product. If it doesn't sell, what makes you think they will put more
development money into an '040 machine? What makes you think they would have
the cash to do so, even if they wanted to? By urging other not to buy and thus
reduce revenues would cause them to be tighter with the cash - and who wants
them to skimp when designing an '040 version? Not me!!!

Besides, you are assuming that an '040 version will be out anytime
soon. Maybe some of those people need a computer in the next few months, not
the next couple of years.

I am not saying that an '040 version would not be right for you, and
you may be able to wait, but I don't think you should neccessarily say that
it is not right for someone else. I know that if I was serious into the
music business, I'd jump at the deal. Even though I'm not, if I didn't have
a TT, I would seriously have considered buying it anyway.

> * this is the exception processing routine
> BusErrHandler move.b #$FF,BusErrFlag * set flag for Bus error
> rte
>*** this is where i get "address errors" when I try to execute a
> RTE from the exeception handler.

For exceptions 2 & 3, there's an extra 8 bytes of info on the stack on
entry to the exception handler. The extra bytes provide info on what type
of memory access was happening (instruction/data fetch, etc). You have to
clean them off the stack before you can RTE. Another issue, one I'm not
as familiar with, is that the return address on the stack may point into
the middle of the instruction that failed, depending on what type of
failure occurred. Logic for returning to the next instruction after the
failure would be complex for a general solution, but I think you can cheat,
since you know the exact place you're expecting the failure, and the exact
instruction that you expect to fail.

Try something like this:

```
BusErrHandler: move.b #$FF,BusErrFlag ; set local flag
addq.l #8,sp ; clean extra info off stack
addq.l #nnnn,2(sp) ; adjust return address
rte ; return from exception
```

You'll need to do a little trial-and-error to get the right value for
#nnnn for adjusting the return address. (Or, get better info from someone
who knows this stuff better than I do. My exception-handling experience
has never included returning to the fail code in this way.)

One other issue is processor type: I have this vague notion that chips
upwards in the 68k family may put even more than 8 bytes of extra info
on the stack -- you may need a couple different exception handlers, and
install the right one for the chip type you're running on.

3263. Adding a hard drive to a MSTe

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-21 21:05:26 UTC
From: "J.J. Lehett" <JJL101@psuvm.psu.edu>
Message-ID: <92234.170526JJL101@psuvm.psu.edu>
Source record: 43112

I have a MegaSTe with the standard Seagate 157N and got a conner 3040a
40 meg drive to add to this. I have a 2 way SCSI cable and power is no
problem. At first I simply replaced the Seagate with the conner and
powered it up. It found it at ID 0 and allowed a forat. However, I cannot
figure out how to get either the Seagate or the Conner 3040a out of
SCSI 0 so that the both can be online at once. The Conner which is last
in the chain has its terminators in and the Seagate never had them in.
I have tried the jumpers on the back of the Seagate no no apparent affect.
The conner has jumpers on the back and also some labled e1-e4 underneath,
and I must have the e4 jumper in to allow it to be formatted (wonder why?).
Do I have to do something with DIP switches in the MSTe to get another
ID available? (I am using AHDI 5.0) Anyone have exactly which jumpers should
be set on the Seagate or Conner to change the ID number?
Any help greatly appreciated!

3264. Getting MiNT/KSH/MW2/GNU C To Work

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-21 22:08:46 UTC
From: scotty@verdix.com
Message-ID: <1992Aug21.220846.26746@verdix.com>
Source record: 43113

I've been trying to put together a development environment based on MiNT 0.95, KSH 04A, MW2, and GNU CC, in order to write an application. While I've printed reams of documentation, I'm having some trouble getting everything to cooperate, and I'd really appreciate it if some of the more experienced users would help me get past some problems.

1. I'd like to start up GEM from MiNT first off, so I can choose between TOSWIN and MW2, or use Uniterm. I achieve this by not having an INIT.PRG, since GEM.PRG is no longer included in MiNT 0.95. Should I be using the old GEM.PRG instead? If I run it, do my environmental variables get stomped on by GEM, or will they be accessible by later shells?

In any case, after MiNT boots GEM, I start MW2 using KSH.TOS -- and it doesn't recognize that it is a login shell -- so I have no environment. I must then manually load PROFILE.KSH and KSHRC.KSH. Is there a better way to set this up? Having to manually load these for each new shell is a pain!

2. When I run GNU Make, all I get is an "Out of memory" message. This is true even when I have nothing loaded besides MiNT and KSH; this is a Mega ST4. Is there another reason for getting this message?

3. Where in the GNU archives on atari.archive is the startup module crt0? I have the GNU libraries and GCC binaries, but didn't get this piece.

4. I'm assuming that I can use these programs without going to a MINIX file-system. Is this still true?

5. How do I start MiNT BASH properly? Will Ver 1.10 work with TOS filesystems? When I ran BASH.TTP from GEM (after starting with MiNT), I had an /etc/PROFILE and used a -rcfile BASHRC (both of these files were defined) in order to bypass the UNIXMODE filenames. What I got was lots of error messages, and only the last several characters of each line in the PROFILE file were displayed. Any ideas what went wrong?

If all of this seems too muddled, I apologize. I've spent a couple of weeks printing out the GNU documentation using CS TEX (great package) and I've dutifully read everything else I could print out... No luck. So far I've just had tantalizing glimpses of what might be possible.

I'd really enjoy seeing someone else's functional setup using some of these programs. All I've had so far is Mark William's C, and I want to start using ANSI C, MiNT, and C++ soon.

Heartfelt thanks for any help straightening this out!

From: JJL101@psuvm.psu.edu
Message-ID: <92234.184643JJL101@psuvm.psu.edu>
Source record: 43114

OK, well in adding another drive to the SCSI chain, I have found it impossible (now I know exactly which jumpers to set for the HD's for proper SCSI ID's) to get anything recognized as other that ID 0 on the onboard SCSI adaptor in the MSTe. Has anyone had success with this? Once again, I added a SCSI 2 way cable to to the adaptor board inside the MSTe, and added the conner in that line, but irrelevant of that, neither the Seagate nor the Conner when appropraitely jumpered will be recogized unless it is at SCSI 0. Is it impossible to actually use 2 'internal' drives this way in the MSTe without resorting to using the DMA port?

> i'm using sozobon, are there books on this subject?

Just never try to access screen directly: it is not compatible to new machines and it is not nice (comfortable) to do. Finally, you never take profit of all the work of OS programmers (or better of NVDI programmers) !

VDI is here to be used ! it may not be the fastest way to draw something but it is convenient !

I used to run a BBS using an HST modem running at 19200 baud, using tos 1.0
and it worked fine. The patch I used to fix the RTS/CTS was TOSFIX 2.2.
The best way to fix this would be to update to at least tos 1.4. then use
the RAINBOW tosfix from atari. The tos upgrade here in the uk is not too
bad (cost wise)

:
: Is hardware flow control properly implemented on the Falcon, I wonder?
:
I am not sure about the Falcon, its weird that its not been fixed in other
versions of TOS.. hohum...

> Even for the simple 68000!
> What do you think are the pins ~BR(bus request),
> ~BG (bus grant) and ~BGACK (bus grant acknowlege) for?

Just a precision: with caches, you generally don't use BG and the likes
to solve the problem of simultaneous access to shared memory: each
processor has his own local bus!

The main problem with 27 processors is that shared memory is not applicable:
this memory would be too of a bottleneck!
but until 10 or so processors, it is definetely 'makable' although
surely (much) more expensive than a 68030 (or even 68040) monoprocessor
system!

That's the whole point: the processor price doesn't decide the system price !

Cheers,

Stefan Monnier

3270. NEC Multisync Monitor

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-22 18:36:22 UTC
From: NCOYNE@ESOC.BITNET
Message-ID: <92235.183622NCOYNE@ESOC.BITNET>
Source record: 43122

I have a NEC Multisync monitor and the question you are waiting for is
can I use this with my Atari 1040 STfm.
This question has probably been asked in the past but I didn't have the
monitor then.
If the answer is yes then please could send me some technical directions
such as pin outs and such like.

Until now I have only been using a TV and I am very excited to have a colour
monitor, so is my son.

Thanks in advance

Nick Coyne

>Do we *know* there will even be one? (Rumors don't count.)

Well, at the Atari Messe in Duesseldorf a guy (his name was
Kreidl or Kreindl) gave a talk about the Falcon. He said that the
Falcon 030 was the first one of a whole family of machines. The
development of the Falcon 040, he added, is well under way.

>Frankly, I don't think a Falcon 040 will come it at the "right" price
>point for a while...

We can only speculate on the price of the Falcon 040, but it
seems to me that Atari has successfully returned to their "power
without the price" slogan after the TT. Let's hope they continue
to do so.

>such as pin outs and such like.

>Until now I have only been using a TV and I am very excited to have a colour
>monitor, so is my son.

The first question to answer your question is: What scan rate is the monitor capable of? ST low res requires 15.75 and most newer multisynch monitors might not go this low. If yours won't you can still get medium and hi-rez. In any event you'll like it ever so much better than the TV.

Pinouts: Looking at the connector from the rear of the computer pin 1 is the upper right hand; pin 4 is the upper left hand; pin 9 is the lower right hand; pin 12 is the lower left hand. If you have the book that came with your ST these should be shown in a diagram at the back of the book. Pin 1 is Audio Out. Pin 2 is Composite Video. Pin 3 is Clock Select. Pin 4 is Mononchrome Detect/Clock In. Pin 5 is Audio IN. Pin 6 is Green. Pin 7 is Red. Pin 8 is Reserved. Pin 9 is Horizontal Synch. Pin 10 is Blue. Pin 11 is Monochrome. Pin 12 is Vertical Synch. Pin 13 which is all by itself at the bottom of the connector is Ground.

I don't know what your level of expertise with electronics is but if you make a wrong connection you could do serious damage to your monitor or computer or both. So please be careful and check your connections twice. This isn't the same as plugging in a drive or some such where it just doesn't work if you make a mistake, so be forewarned.

To help we probably need more info.
Ie, do you have an internal or external disk drive?
What kind of monitor are you using?
can you hear the drive at all?
Put a formatted disk in before you turn the machine on,
hold your finger just touching the disk. Can you feel the drive
vibrate?
Hav you checked all the trivial little things, like connections
the monitor brightness dial at the back, etc.?
What exactly does it say just above your numeric keypad?

If you have just 520st over the keypad, And an external disk drive then
it's one of the earlier machines and may need tos on disk to run.
There should be a label on the underside of the 520. What does it say
as far as the model number goes?
Did you get a grey labeled disk with the machine with the word "TOS" on
it? if so you need to boot with that.
If the label underneath says 520STm then you can hook it up to your TV
with a connoector like those that came with the old 'Pong' games. Try
that. Maybe the monitor is fried.

Give full details of your system when posting messages for help.

good luck.

Source record: 43125

Well this is the reason why I have been bitching about Atari..

We no longer have any active shops selling Atari Computers and no
software sales at all, and this is in ALL New Zealand..

You are also unable to get you computer serviced as there is no one
providing parts any more..

There is one group of shops selling the Lynx game console,
but that does not sell to well here, the Game Boy has it all over
the Lynx here, sold in more shops and is Advertized on TV..

I have also been told that Atari OZZ will no longer be selling
the Atari computer range, only the Lynx.

Note: There is still a lot of shops selling the Amigas and even
the new A600, plus you can get all the latest software for the Amigas here.

The level 2 of the Falcon will be some two times the price of good 386
clone, and with monitor, so I can't see the Falcon selling here at all..

PC clones are very cheap here, but the software is very dear, some 5 times the
USA price...

..Any body wan't to lend me some the moneny so that I can get a PC Clone..:-)..

That's no question if the monitor is working, 'cos then you get a screen filled
with atari symbols and colours flowing down the screen. That's an indication
to whether you have to use a boot-TOS or not.

Jarle.

3277. ??? 10 Meg Bernoulli : Anyone using one on STf

s>1. I'd like to start up GEM from MiNT first off, so I can choose between
s> TOSWIN
s> and MW2, or use Uniterm. I achieve this by not having an INIT.PRG, since
s> GEM.PRG is no longer included in MiNT 0.95. Should I be using the old
s> GEM.PRG instead? If I run it, do my environmental variables get stomped
s> on by GEM, or will they be accessible by later shells?
You won't need GEM.PRG any more. If you have no INIT in MINT.CNF, MiNT will
start GEM. Your environment variables will be accessible by later shells.

s> In any case, after MiNT boots GEM, I start MW2 using KSH.TOS -- and it
s> doesn't recognize that it is a login shell -- so I have no environment.
s> I
s> must then manually load PROFILE.KSH and KSHRC.KSH. Is there a better way
s> to set this up? Having to manually load these for each new shell is a
s> pain!
Just put something like
setenv ENV c:\mint\kshrc.ksh
in your MINT.CNF. KSH will load this file every time you launch it.

s>3. Where in the GNU archives on atari.archive is the startup module crt0? I
s> have the GNU libraries and GCC binaries, but didn't get this piece.
You need the sources for the GNU Binaries; there you will find crt0.

s>4. I'm assuming that I can use these programs without going to a MINIX file-
s> system. Is this still true?
Yes!

Bye

Christof

> which didn't solve the problem.
>
> Anyone?

I bought an external 1.44Mb drive on the Atari Messe last weekend and it worked!
I then concluded that it must be the drive it self which was the problem.

After a long time of discussions with a friend of mine, I reopened the TT's case
and replaced the drive. It still wouldn't work, which gives me the creeps,
because the external one did. When we looked at the time, around 1:30 AM :-(,
we gave up and closed everything again. We couldn't resist a last try, and.....

it worked. It seems that it is very important to close the case. Interference
of the monitor? who knows,

Anyway, I am now the happy owner of two 1.44Mb drives.

Thanks to everyone who posted or mailed some help.

3284. Vanishing partitions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-25 17:03:13 UTC
From: ken@isgtec.com
Message-ID: <3173@isgtec.isgtec.com>
Source record: 43131

Well, after thinking "it'll never happen to me", it has. I can't access
any partitions on my hard disk. I was working on a program for a few
hours (of course), compiled it, ran it, and boom, 4 bombs, machine reboots,
and I'm looking at just drive A and B icons. I tried some obvious things,
cold boot, turning computer off and on after a while, no go. Ok, powered
down everything for 1 minute, then hard drive on, then computer on, same
thing, just A and B icons. So I figured the boot sectors on drive C must
have been zapped, so I ran ICDBOOT.PRG from a floppy, it seems happy,
I install a drive C icon, click on it, get "Drive does not exist...".

So, in summary, I can't get at any partitions on the drive. Can anybody
suggest something? Surely I haven't lost all the partitions? I don't care
if I lose the C partition, it's backed up. But the whole drive? I don't
want to start repair/recover utilities until I try some other alternatives.

Hardware: ICD ADSCSI+ adaptor, ICD software, Maxtor 120 meg scsi disk.

advTHANKSance.

When booting up one's ST, doesn't one usually switch the monitor on first? I've been doing this for quite a long time now, but it doesn't seem to work anymore. Let me explain. If I switch on my monitor, then my 1040st, the screen will stay totally black, and when the desktop appears, it will be colored some odd purple, be totally twisted an bent looking, and after about half a second, will dissapear altogether. BUT, if I then proceed to switch the monitor off, and then on again, everything looks peachy-keen. Argh.
I've got a 1040st, SC1224 color monitor, a DS internal drive, and a SF314 hooked up as a second drive. Any ideas on what's up with my ever-so-odd monitor problem?

If memory serves me right, GEM uses trap #2 for AES and VDI calls.
If FORMDOIT (which makes fly-dials, I think) would mess trap #2 up
somehow, this would serve as an explanation.

Why would you need an adaptor to put an Atari hard disk on a SCSI port?
Just remove the host card and connect the drive (or SCSI controller+ST506
drive) directly to the Falcon SCSI II port.

What is going on here? If you want to write a screen saver you should
intercept the IKBD vetcor at $118 but the code that does so should not touch
$FFFFFC02 at all! The fact that the interrupt has occurred is all the
information that is required. Basically you could intercept the 200Hz clock
vector ($114?) and just add 1 to your own private clock variable. When your
clock var hits a predetermined limit you blank the screen. The IKBD intercept
code just needs to zero the clock var and restore the screen if it's
currently blanked. As long as there is IKBD activity (mouse or keyboard) then
the clock will never reach the limit.

Bung in XBRA's before your intercepts and put a cookie in the Cookie Jar so
that the delay can be altered and well you've got something very similar to
Ken Badertscher's Maccel3.

3289. Detecting 'Carrier Detect' line

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-26 09:21:10 UTC
From: andre@cix.compulink.co.uk
Message-ID: <memo.594261@cix.compulink.co.uk>
Source record: 43135

Can someone tell me a *legal* way to test the 'Carrier Detect' status of a modem on an RS232 serial port? The method must be able to work for all serial ports which support the DCD line (including the additional Mega-STE/TT ones). I assume this rules out using the MFP interrupt - and anyway, I just want to test for it periodically, rather than have an interrupt handler continuously monitoring it.

Thanks,

Andre

Why don't you use Let'Em Fly? Most dialog boxes will behave like Flydials,
i.e. you can move them and use Alt+key combinations instead of mouse clicks.
You can get it from a.a.u.e. (I think the docs are German, but the CPX is
English, so you won't have too many problems using it).

>wonder why these routines crash the system with FORMDOIT
>installed?

I don't know, but obviously it's a bug in the trap dispatcher.

Ulf

Hi,

All I can say about the problem (SC1224 has a dark purple picture when switched on before the ST) is that I have had exactly the same problem for a year and a half now.
It seems that the monitor doesn't like it when it gets no sync signals.
This I found out when I tried a 'smart' screen-saver which just stopped the sync. This type of program is no fun, as I don't know if it can permanently damage the monitor.

Something which works for me is switching the monitor and computer (and HD) on at the same time (I use a large power strip with its own switch).

Good luck,
Bart Schuller

>The correct termcap entry for tw52 is the one put into the TERMCAP=
>environment variable by TOSWIN. You can also retrieve it by sending
>ESC T to TOSWIN from one of the windows.

If I open a TOSWIN window with MINTSHEL running inside, 'echo ESC-T' bombs out
the shell; I finally tried it on a minimal system; nevertheless the
problem didn't disappear:

This is a MEGA-ST1 with (German) TOS1.4.
I prepared a disk with only the following files on it:

AUTO\MINT.PRG
TOSWIN.ACC
TOSWIN.RSC
MINTSHEL.TTP

After system startup, open TOSWIN, create a std window with MINTSHEL in
it (no args) and enter 'echo ESC-T'.
In response, I get something like
pid 3 (MINTSHEL): BUS ERROR: PC=456205c (basepage=759d0)
The TERMCAP string gets printed, then MINTSHEL exits.

3295. Minit and echo * problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-26 15:49:25 UTC
From: bq035@cleveland.Freenet.Edu
Message-ID: <1992Aug26.154925.6753@usenet.ins.cwru.edu>
Source record: 43140

Hi. I've just experimented with minit.ttp on one of my small partitions to see if it was something I'd like. But I'm having trouble getting all the filenames recognized by a shell. I've used init, ksh, bash, and tcsh, and so far, the only shell that will correctly return all the full length filenames when I echo * is tcsh. Using ls from the futils is no problem, I get all the files listed. But if I were to ls *, I would have a problem. The expansion seems to only be correct in tcsh. However, I have noticed that in the root directory, the shells seem to do ok, and even with init, bash, and ksh, *some* filenames get expanded okay, even in subdirs. I use mfsconf to set all short name replacements to neither (-l n -s n -d n -x n ? I can't remember if it's a n, but you get the jist, I'm not at my Atari now), so as to always have the full names.

Has anyone else dealt with this? Is it some subtle thing I'm missing? Any help is greatly appreciated.

3296. Re: Intterrupts for screen saver ...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-26 18:25:56 UTC
From: ramaer@cs.utwente.nl
Message-ID: <1992Aug26.202556@cs.utwente.nl>
Source record: 42947

If you steal a vector, you should use an XBRA chain.
See e.g. archive.cs.ruu.nl:misc/xbra.zoo for an explanation.

An interrupt routine must preserve ALL registers, so I prefer
to write it in assembly:

```
.text
.globl _sense_activity
_sense_activity:
.dc.b "XBRA"
magic: .dc.b "mine"
oldvec: .ds.l 1
new: move.w #1,_keyboard_is_active
move.l oldvec,-(sp)
rts
```

Now the global int keyboard_is_active is set to TRUE each
time an interrupt arrives (watch out, not only for keypresses
and mouse movements but also for timer packets and midi.)
A timer routine may test and clear this variable:

```
timer()
{
if (keyboard_is_active) {
if (screen_is_saved)
unsave_screen();
keyboard_is_active = FALSE;
counter = delay;
} else {
if (counter == 0)
save_screen();
else
counter --;
}
}
```

Watch out! If you use external synchronisation to make the screen
black then you can not make 'timer' a VBL routine because with
external synchronisation there will be no more VBL's.

Hope this helps, Mark

Actually I said or.w d0,(a0) _type_ instructions. By this I also mean
and.w d0,(a0), eor.w d0,(a0) ... The code does proper masking.

|> <delight> if you can mail me code-for-code patches, I'll put them into
|> my library (which will be free-to-all one of these days).

I'll do that as soon as I have some time. The main problem is that I use moto
memonics & your code uses MIT memonics (which I can read (to calculate the
timings) but not write (reliably)). Also what regs does gcc (a) use to
communicate with the asm stuff (b) leave free for the asm stuff - I need all
8 data regs!
BTW when I write hybrid C/asm code I always put the asm in a separate .s
file and pull my own arguments off the stack.

|> Actually, I think it was more like 50 at 72Hz (ie. mono).
|>
|> >Still I can't resist the challenge...
|>
|> You didn't post performance stats! How well does it BURN?

Oops - you didn't say mono - the last routine I posted was for single plane
lores sprites (any plane). Mono should be faster because you don't have
skip over unused planes & can make use of long word ops.

|>
|> Let's make some categories:
|>
|> 1. Preshifted / Unshifted

I'm looking at upgrading to a letter quality 24 pin dot matrix printer but am thinking that it may not do screen dumps correctly. Not that I do a lot of screen dumps myself, but some of the software I run does (easier than writing their own printer drivers, I guess).

Is there a PD driver I can install that will allow me to dump to a 24 pin printer?

Brian Rost @rgb.enet.dec.com

Isn't MNP usually a function of the modem firmware? Or if you have this MNP software and an old or cheap non-MNP modem, I suppose it means you don't need to buy a new modem. In case you really have an old or cheap modem, which is better - get a new MNP modem or buy the MNP software?

Check out the Canon BJ10ex before you do - it depends on your applications.

The BJ10ex has 360x360 dpi (more than a laser printer, but slightly large
dots, so not quite as good output), and emulates a few printers - it can
even handle a screen dump from the ST (using the ST's Epson printer config).

The best thing about the BJ10ex is that it is SOOO small and SOOOO quiet!

I don't believe it is possible to implement:

move.l (a0),d0
and.l d1,d0
or.l d2,d0
move.l d0,(a0)

more efficiently without the use of the d0 temporary. Certainly it won't
be more efficient on anything with a cache or a fast CPU (relative to bus).

3304. Re: 24 pin screen dumps

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-27 06:06:11 UTC
From: hohr@dxcern.cern.ch
Message-ID: <1992Aug27.060611.20884@dxcern.cern.ch>
Source record: 42953

Direct mail bounced. So I send it here.

Hi Brian,

I did write (a long time ago:-)) a utility for screen dumps with my 24
pins printer. Here's it's READ_ME file:

-------------------------cut here---------------------

HC24_H12.PRG

This utility replaces the internal hard-copy routine (for 9 pin printers)
by an other one for LQ500 compatible 24 pin printers (high resolution only).

In addition, it respects the x/y ratio (circles on the screen are also
circles on the paper) and it will give you a realy good printout of about
180x115 mm. in horizontal format.

The negative parts are that you need a printer spooler of 128kb, and that
it will thake about 23 seconds on a Mega STE (at 16Mhz+cache) before you get
the hand back, even if it is, like this version, compiled with the Pure-C
compiler (Thanks Ulf).

To be put in your \AUTO\ folder. Use it at your own risk: it's absolutely
free. If modified, please let me know. Not to be sold or for commercial use.
I just hope it works for you too.

Enjoy!

Roger email: hohr@cernvax.cern.ch

-------------------------cut here---------------------

It's on a.a.u.e in the directory printing.

Have a nice day.

3305. The ultimate sprite routine, Generated code and the other one..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-27 08:33:19 UTC
From: amos@prl.dec.com
Message-ID: <1992Aug27.083319.11106@prl.dec.com>
Source record: 42954

For color monitors (4 bit-plans)

Less memory :

In fact, the best routine before the generated code was the preshifted one, but
I've got an optimisation :
Let's say you preshift 16 times a sprite, and also the masks.
For the masks, you should also have twice the same mask for 8 bytes, (so a mask would take
4 bytes instead of 2..)

The routine would go like this :
lea mask_predecal,a0
lea Sprite_predecal,a1
lea Screen_address,a2

you have the x and y, in d0-d1
so y*160 + (x >> 4) << 3 for the screen offset, and (x && 15) for the sprtie decal pointer.

then x*sprite_size to point on the sprite shifted at (x && 15) position, + a1

then movem.l d1-dx/a3-ax (x for left registers you have)
move.l (a0)+,d0
and.l d0,(a1)
or.l d1,(a1)+
and.l d0,(a1)
or.l d2,(a1)+
... for the sprite size .
So here, you have optimized and with the movem, and with the double masks..

Generated code, the best, but it takes a lot of memory:

Let's imagine the sprite. If you poke as warwick@cs.uq.oz.au (Warwick Allison) said,
directly the code at the screen with the masks like :
and.l #xxx,y(a0)
or.l #www,y(a0)
...

And if you generate this code, instead of typing all the xxx yyy zzz too many times..
you generate the and.l #xxx,y(a0) in memory (I do not remember how it is exactly coded..),
then you would have to jump in the address where the sprite is printed !
So you make a routine that looks at the sprite, and generate and.l and or.l, and shifts
the sprites, then you look at the x offset and just jump in the routine you have made in
the beginning of the program. Now, the other advantage, is that when you see that the
sprite
has 16 black pixels, as it is a sprite, you generally and.l #$ffff,(a0) or.l #0,(a0)
so here you do not and anything and just increments a0 ! you save precious cycles..
If you want to push the routine as its best optimization, in your routine at the begging

you redraw the sprites : try to see the 4 colors that appear the more in the sprite, and put them on different plans, the other colors on the 11 left colors, then you would often have only to or.l 1 plan (but still masking 4) because the color is always in his 16 pix. blocks.

By re-reading me, it looks very confused. If you want more information about generated code, or
a source, just ask it..

The results are : on a 8Mhz STf, 20 32*32 sprites in 1 VBL ! or huge sprites.. very cool

Amos.

Source record: 42958

I am having problems running the Hybrid Arts ADAP 1 software on a Mega STE. On a regular ST, I can zoom a window and then evelope a small section of a waveform. On a Mega STE, the window zooms back out. I have eliminated software as a variable, and now look to the ROM routines as the probable culprit. So the question is, can I load TOS 1.x ROMS in place of the 2.x ?

Please E-Mail response direct; I'll re-post appropriate info.

Thanks!

I TOTALLY AGREE

I am not using MiNT at the moment, because something with my GEMINI goes wrong, but I'm working on the ST text editor of the future, which makes use of the right mouse button to work in background windows. It is very annoying that mouse events are usually (at least not on my STE) not sent to background windows if the top window is not owned by the same application (I am talking about DA- multitasking now).
I sure wish this is going to change in MultiTOS, which is after all at the moment a more vital concern to all of us than just MiNT, I think.

3308. The gawdawful menu bar and a moving mouse

Newsgroup: comp.sys.atari.st.tech
Date: 1992-08-27 13:29:37 UTC
From: avgroeni@cs.ruu.nl
Message-ID: <1992Aug27.132937.17637@cs.ruu.nl>
Source record: 42963

First, a reaction on the ACCs Die! Die! article. Yes, and because
of the fact that only accessories will not have that awful menu bar,
people should stop writing applications. I hate to look forward to
a system that works like Mac 7.0: if you top a window of a new application,
the whole desktop and menubar are redrawn. This is ridiculous, but for
compatibility with programs that use a WF_NEWDESK or menu bar,
necessary.
A friend of mine (Wilko Quak) wisely remarked that it would have been
MUCH better if GEM worked with a co-ordinate system relative to the
work.g_x and work.g_y of the window one is redrawing. Then, the conventional
desktop could have easily been replaced by a desktop in a window.

And now for something completely different:

How do manually (that is, without using your hands) position the mouse?
Example: Turbo ST automatically puts the mouse arrow on the OK button
of its alert box! Can this be done, how, and does it confuse the AES?
What I'm thinking of is, when you touch a direct-reaction scroll bar
such as used for example in the Gemini Dialog boxes, can you make the
mouse go up slower, thus increasing the number of mouse 'dots' needed
to scroll through the whole text and hence increasing the resolution of
the scroll bar.

>their own printer drivers, I guess).
>
>Is there a PD driver I can install that will allow me to dump to a 24 pin
>printer?

Brian, unless someone really has the need to print onto multi-part forms, I fail to see why anyone would want to buy a 24-pin dot matrix as opposed to one of the modern inkjet printers. There is close to no cost differential and the benefits offered by the inkjets are substantial, IMHO. They are quiet and output gorgeous quality 300dpi that is very difficult for the untrained eye to distinguish from true laser output.

The Canon BJ10ex has been touted here, and it _is_ a nice printer. However, one must be careful of overzealous claims made by manufacturers and enthusiastic users. The Canon's claimed 360x360 dpi resolution really ain't so as the dots are staggered (such as they are on 24-pin dot matrix printers). You still end up with an effective 300dpi, mind you, but better than a 300dpi laser? Not.

The Hewlett Packard DeskJet 500 (and it's color sibling, the DJ500C) are more widely in use than the BJ, due in part to the PC and Mac versions available. Numerous font and emulator cartridges are available as well as ink refill kits (black or in colors) which lower overall cost of printing. The HP DJ500 is larger than the Canon BJ, but equally quiet and reliable.

All inkjet printers are slow, but only in comparison to a true laser. If you NEED to print on multi-part forms, get the 24-pin. But otherwise, jump for one of these two inkjets if you cannot afford a true laser printer.

In the end, "You pays yer money and you takes yer choice."

I agree that an 'jet type printer is best for graphics, but I humbly submit
that there is a place for fast dot matrix printers.

I use both, with the main job of the dot matrix being to print programs and
documentation on fan-fold paper. It is much easier (for me) to use printouts
that continue from one page to the next and always stay in sequence. A simple
A/B switchbox allows me to go from one to the other as needed.

On the subject of jet printers, its also possible to get 'personal' duty
laser printers for less than $500 now, so they might be an alternative to
using INK technology. Personal duty being 4 pages per minute or so, like the
Okidata model.

>have been zapped, so I ran ICDBOOT.PRG from a floppy, it seems happy,
>I install a drive C icon, click on it, get "Drive does not exist...".

I used to run a ST BBS here in England, using the same controller card, but
with an Seagate drive (40megs/57formatted)
One day my system did the same thing. I have been told that its something
to do with the way the ST talks to the DMA port.
I was also told that if I reduce the size of the first partion (logical drive
C:) to its mimium size, and if memory serves me that was 1.8Megs this would
reduce the chance of this screwup again.

>So, in summary, I can't get at any partitions on the drive. Can anybody
>suggest something? Surely I haven't lost all the partitions? I don't care
>if I lose the C partition, it's backed up. But the whole drive? I don't
>want to start repair/recover utilities until I try some other alternatives.

In some cases the manual for the adscsi card said that you can re-create the
partion information and so recover the drive, in practic I have not been able
to do this. and it ment a re-format (hence the death of my BBS!)

Sorry this is not to positive..

Well Computer Shopper the UK version some months back, had a good article
and reviews of a range of printers, but did point out one big problem with
Ink-Jet Printers that they are only good for out line art, they have no
grey scales..

The one printer at the low end that did was the Oki 400 Lazer Led printer,
this was very good for grey scales and in the print out of the pictures
in the review, as to the samples shown for the Ink-Jet ones..

Roger..... sheppard_r@kosmos.wcc.govt.nz

|> I have a very basic question regarding Minix/Mint. First what exactly
|> is Minix (my assumption is it gets you around the filename.ext filename
|> limit, but what else). Also, is it shareware/pd or commercial? And
|> how would one create a "minix partition" and access it? Thanks...

Absolutely not!
MinT was, originally, a multitasking (X)BIOS & GEMDOS for TOS. ATARI used this as platform for
MultiTOS.
MINIX is a complete different OS much UNIX alike (i.e. System 7). Thus, it is possible to have more than 8+3 chars and as much as '.' you like for yer file.
As far as I know, it is commercial, but I guess the updates are free in every meaning...
To create a partition, pre-format yer disc under TOS and part' it as you like, reboot (MINIX)
and type (e.g.) /etc/mkfs /dev/hd1 1024
that means "make filesystem on device hd1 (i.e. partition 1 = c) with 1024 Bytes"
U see it is similar to UNIX we use here, except pre-formatting using TOS.

sincerely,
Chris

3319. Documentation writers needed

Newsgroup: comp.sys.atari.st.tech

>
>I TOTALLY AGREE

Part of me agrees; it's just that the current "system" doesn't work very well. It's definitely NOT completely sensible!

The problem occurs when one window is COMPLETELY obscured by the another. For instance, suppose I have the TOSWIN window covered by the TCSH window. I can't SEE the TOSWIN window - why should its menus activate when my mouse hits the (HIDDEN) spot where the TOSWIN is hiding? You can improve the rules, but the status quo has a problem, and this is where it lies.

Someone mentioned the DCTOPPER program; that is a utility that forces the window on which the mouse pointer lies to become the "front" window. That is a way of making the system WORK, and do what you'd like. Ideally, the features of DCTOPPER should go into TOS/MiNT/MultiTOS/whatever, preferably as an OPTION, and not as a mandatory feature (ala X-windows, where you can customize the environment...)

Well, that's interesting, Roger, because I've got some nice grey scales out of my HP DeskJet Plus using FSM GDOS. Now this wasn't anything real complex, mind you, and I don't mean to imply that an inkjet will ever compare with a good quality laser, but they _can_ do some grey scales (at least mine can). If you have it, try the test print program that comes with FSM GDOS. You can print a nicely shaded checkerboard using it with a DeskJet. Not that everyone needs or wants to mess with GDOS at all, mind you.

Maybe it has more to do with the printer driver than the printer itself, eh?

Ah, yes... I forgot about program listings. I use my old tried-and-true Epson
FX-80 for that. But you don't need a 24-pin unit for printouts, do you? In
my mind, speed and low-cost is of the essence for that kind of job.

Also agreed, but prospective buyers should beware of lasers that are TOO cheap.
The inkjets are a good compromise but if you can find a great deal on a laser
with the emulations and features you need, then jump on it!

Hello.

I am looking for information on ANSI/VT-100 so that I can include it in the next version of ShadowTerm. I have as yet not been able to locate ANY information on the subject. I am mainly looking for a method to interpret the codes sent. I can obtain a font fairly easily, but I need to know the codes.

(I have no access to mail-servers or FTP, so please do not respond with a suggestion to download the information from atari.archive or an FTP site...<Grin!>)

Any information would be appreciated.

The Motorola 56001 DSP is a general purpose Digital Signal Processor.
Probably the easiest way to think of a DSP is as an ultrafast math
coprocessor. The NeXT uses the same DSP and uses it to do things such
as emulating high-speed modems (a 9600-14400+bps Fax/modem is in the
works for the Falcon for around $100), handling high quality digital
audio, and various other tasks. The NeXT is a popular research
workstation due to the abilities of the DSP in calculating large amounts
of data. There's also talk of using the Falcon's DSP for decoding and
outputting Dolby Surround Sound. The DSP could also be used to make
flight simulators which rival even the best arcade games (ever see STEEL
TALONS?).

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi.

In my never ending quest to compile the Zmodem 1.62 source code, I have run across several problems.

There are repeated references to a PD MAKE tool. I do not have this tool, and have never been able to locate it. Is it GNU Make?

Also, how do you find out what version of Alcyon you have? I bought the developer's kit from Atari, but can not find any mention of a version number.

Boy, isn't C fun? (As you might have guessed, Pascal is the language for me. It seems to much easier to grasp.)

Last question: The DLIBS library is mentioned in the docs, in association with Alcyon C. I thought DLIBS was meant for Sozobon C? I have a version of DLIBS, but now I'm not sure at all what I should be doing to get Zmodem compiled.

By the way, the Zmodem archive came from GEnie and it is labelled 1.62.

Any help would be appreciated.

Another reason is that you just shouldn't use machine- or device-dependant
tricks: who knows if this very same location will have the same purpose on,
say, the Falcon ? or anything else ?
The only case where it is useful, is when you WANT to write a machine-
dependant program (such as an OS replacement)!

How nice it is to see YOUR program working on a completely unknown
machine ! It is "jouissif" (don't worry, it is in french)

Well, first of all you'll destroy all packages sent from the keyboard processor since when you read/test $FFFFFC02 (for example) you'll also 'tell' the keyboard processor to put a new value in the register. This will cause the mouse/joystick to behave VERY strange. The only task that should read/test $FFFFFC02 is the OS itself (or you should AT LEST never let more than _one_ task read/test it)! So unless you rewrite the whole OS-routine for keyboard-reading you shouldn't touch $FFFFFC02!!!

One should ALWAYS be extremely careful when dealing with memory-mapped registers from OS-friendly programs (and a screen-saver should be at least 100% OS-friendly! :-).

I have. It doesn't seem to matter what else is running, but I find
that the TOSWIN menus drop down even when the TOSWIN window is completely
obscured. I'm learning to live with it though.

Another thing that disappointed me slightly was that TOSWIN crashes on
startup if MiNT is not running.

Source record: 42983

Emacs 3.10s will not compile on my Laser C compiler, and I am therefore unable to tailor the program to my liking. atari.archive.umich.edu has a version with no color, with no reverse status line, and with incremental searches enabled.

Would it be possible for somebody to compile and link this for me to produce a normal, GEM desktop executable program with these options:

```
Option Setting Define in "struct.h" (may not be correct)
---------------- ------- ----------------------------------------
Color on #define COLOR 1
Reverse status line on #define REVERSE 1
Incremental search off #define ISEARCH 0
```

If you are kind enough to help me out with this, please send me a short reply using private email telling me that you could do it, and I will give you the go ahead. In this manner, I won't get ten copies and have nine people waste their time.

Thank you very much, Max

Okay, but how do I get Alcyon to use DLIBS instead of the library it uses
now (which seems to be nothing special). My only experiences with "make"
so far have been ones of total anger, since I can not get it to do what I
need. For a while I thought I was on the right track, but then it told
me that all of the files were up to date. No matter how I changed the
dates on the files, it held to that position...

Hmmm again. What is your system configuration? Often, I press the right shift
key to bypass MiNT, and the only thing that TOSWIN complains about is
that it cant get a pty. This is due to TOSWIN.CNF starting up BASH and TOP
automatic upon startup...

Im extremely happy with TOSWIN. But there is a point that I should
state. When I try to start Elvis with a filename, it crashes the system.
But if I start without a filename, and use the internal read command, it
works fine. Nothing that really bothers me, tho

Last week my Seagate 296N decided that it wanted to keel over and die. I've had the drive for close to 5 years, and used it nearly every day then.

The drive wouldn't spin up, until I turned the platter. I figured the lubrication gummed up the heads and was preventing it from spinning. (I spun the platter via the ratchet disk on the bottom of the drive, not by opening it up.)

However, when the hard drive spins up, it blinks the drive light eight times. My computer reports that it can't find the drive on the SCSI port, so I can't re-format it or otherwise salvage it via software tools.

I know that hard drives have a limited lifetime, but it's a bummer that it only lasted 5 years wheras my other 3 MFM drives (on various computers) lasted 8 years and are still going strong.

Is there any hope for this drive, or is it only good for an art project?

If I have to buy another SCSI drive, is Seagate a good brand, or should I consider a different brand?

Thanks,

Derrick

Source record: 42897
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

When I did the upgrade from 0.94 to 0.95 I hit two little bugs in the
news version:

1) When a filesystem (minix.xfs) is in / instead of in /mint, it gets
loaded twice (at least I see the copyright notice of minix.xfs twice).

2) There is something wrong with cursor handling when using
/dev/fasttext, which used not to be. The cursor is not blinking
anymore, and when I hit return often the black spot remains on the
last line. Also, in an editor the cursor often is not visible at all.
Note that this did not occur with TOS things like gulam, but with my
version of bash and microemacs; I compiled these for the plain unix
version (which works fine and is nicer than the TOS versions).

I'm having trouble with my Atari 1040ST, TOS 1.4 recognize my external disk drive. When I try to get the disk directory, it would display:
Drive B: is not responding
Please check the disk drive
or insert a disk.

The disk is okay on my internal drive. The drive mechanism is a TEAC drive. There are a bunch of jumper settings which I have no idea what it should be set to.

They are US1, US0, RE, M1, M0, MS, D3, D2, D1, D0, and FG. I figure the D0-D3 are the drive selectors, but I don't know about the rest of them. Currently, I've closed the MS, D0, and FG jumpers. Any ideas what it should really be set to.

Source record: 42895

In <H.H8xksAVnXI6@kynes.bison.mb.ca>, Russell Ochocki writes:
>There has been several threads discussing how great it is to have DSP in
>the Falcon. I have read all these articles, but don't have a clue what DSP
>is or what it does?
>
>Can someone enlighten me?

I received an excellent answer in the mail from R_Tim_Coslet@cup.portal.com.
It follows below. If you don't have a clue what DSP is, this article is
for you! Read on...

--------------------8<----------- cut here ------------8<---------------------------

R_Tim_Coslet@cup.portal.com writes:

DSP stands for Digital Signal Processing or Digital Signal Processor.

Originally DSP was developed arround "sampling theory" (which was developed
in part by a guy named Nyquist sometime in the '40s thru '50s, if I remember
right) as a means of performing the same Signal Processing operations
(e.g. filtering, spectrum analysis, mixing, signal corelation, etc.) as had
been used in conventional Analog based systems. Because Digital methods
are used, one gets "exact mathematical" results instead of the often noisy
and distorted results common in analog signal processing systems.

Of course DSP techniques have their own limitations, and introduce their
own characteristic distortions. However these problems are much more well
behaved than the problems in analog systems, and one can be reasonably
sure that each increment of added investment and cost in a DSP system
will produce a corresponding increment in performance and reduction in
these distortions; one can NOT be sure that an increase in investment
and cost in analog systems will produce ANY increase in performance and
reduction in their noise and distortions.

DSP being a "real time" technique (if you can't keep up with the REAL signal
you can't expect to process it and produce a reasonable result) is very
demanding of mathematical resources and throughput speed. This has pushed
the development of custom Digital Signal Processor computer chips, with
very high speed ALUs and often considerable internal parallelism.

It turns out that many other areas of computing are also demanding of
mathematical resources and throughput speed, but because they don't have
the market "push" behind them of DSP users (e.g. telephone systems, modems,
music, radar, sonar, instrumentation manufacturers, etc.) have not been able
to fund as much development of custom high performance processor chips
optomized for their uses. As demand has pushed the suppliers of DSP equipment
to produce inexpensive DSP chips, these other areas of computing have found

the power of the DSP chips relatively easy to adapt to many of their uses too,
so although the chips were developed for use in signal processing functions
and are still called DSP chips they are often used anywhere where very
high speed arithmetic is needed in a computer.

Does that make things any clearer?

Well the best thing about a 56001 is that it has a hardware multipler which can
do a multiply & add step in 1 instruction cycle (= 2 clock cycles).
This is much faster than your typical microprocessor and in fact the 56001
does shifting via multiplication rather than the other way arround.
Other goodies:
3 memory areas (1 program, 2 data) which can be simultaneosly accessed.
With most instructions you get 1 or 2 move instructions free.
Fancy adressing modes for fast circular queues, FFTs etc
Fast interupts
Hardware looping

Things which the 56001 should be useful for include software sound synthesis
& matrix*vector multiplcation (the basis of 3D vector games).

If the DSP DMA is implemented right (does anyone have a programmer eye view of
this yet?) is should be possible to use it as an extremely fast graphics
processor for polygons/phong shading/texture mapping (I wonder if anyone
will bother to write an "Ultima Underworld" type game for the Falcon?).
I worry about this though - the DSP is 24 bits and the 68030 is 32 bits
so there's plenty of room for Atari to screw up...

Steven

3344. STE specific info needed!

Newsgroup: comp.sys.atari.st.tech

I am to become a proud owner of STE. However I don't have any
information about ste's new features (mainly graphics and sound).
Pointers and/or information would be greatly appreciated.

And one technical question: what may I connect to those audio ports? I
have a pair of active speakers, is there any easy possibility
connecting those (meant to be connected to haedphone port) without
frying anything...

Thanks in advance,
/hysky hysky@utu.fi j.h.husgafvel

If you have your dependencies set up correctly, touching your .c files so that they have a more recent date ought to generate a recompile by make. You can always remove your .o files and then make has to recompile them.

Makefiles are ugly beasts to hack (I'm thinking UNIX and VME systems mostly) but once you get it set up, make sure makes life easier.

What you'd want to do is to connect them to an amplifier, which then gets hooked to a set of speakers. They produce quite nice stereo input; there's not enough juice in 'em to run any substantially sized speaker - I really don't know the impedance. You should be able to hook 'em up to a set of headphones. Make sure you have a potentiometer in between for volume control (unless you want to use the CPX to control volume). You MIGHT be able to hook up a SMALL pair of speakers. You'd be better off hooking it up to the stereo system, tho.

For anyone who hasn't seen the latest AEO, the Falcon appears to
have been design as a 24 bit computer, partly to maintain compatability
with existing software. This doesn't mean third party boards etc can't
extent that, but it explains the 14 meg memory limit. The other captures
from Jim Allen posts to GEnie say that the Falcon chips all seem to talk
at 16mhz. Another poster mentioned here that there's an 8bit processor to
dsp channel, I guess for uploading code into the dsp, though I don't
know if that means you can't tell the dsp to load a program from a memory
location itself, which would be faster, I'd guess.
Motorola says the top speed the 56001 is clocked at is 33mhz, so the
ad/da converters must be the parts clocked at 50mhz.

3348. ZOO/ZIP/ARC/LZH

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-01 01:43:04 UTC
From: Steven.Wells@bbs.actrix.gen.nz
Message-ID: <1992Sep1.014304.22255@actrix.gen.nz>
Source record: 42902
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Here is a comparison of the four most used Archiving utilities on the Atari ST (And indeed - most 16 & 32 bit machines)

It was performed on an Atari 520STFM with 1meg of RAM. Using a 300k FAST-RAMdisk for all file operations. Write verify was turned off. No TSR's or ACCessories were loaded.

Results may differ very slightly on some machines. (Speed will obviously increase when being used on accelerated machines)

Comparisons of, ZOO, ZIP, ARC and LHarc are described below. This is using versions, that to my knowledge are the latest versions available to the general public. It is not definitive, but it gives a good idea of which techniques are best to use when you want quick & effective compression - (or slow and in-effective). The results are quite surprising with the popular LHarc coming after both ARC and ZIP in the overall ratings, and being beaten by the default compression mode of ZOO!!

De-compression has not been tested - as times are usually pretty similar in rating.

Text: (181246 bytes)

Time taken:

ZOO (Default) 44 secs
ZIP (Default) 45 secs
ARC 46 secs
ZIP (Deflate) 51 secs
LHarc 74 secs
ZOO (Slow mode) 100 secs

Compression: (% of original size)

ZIP (Deflate) 33.5
LHarc 35
ZOO (Slow mode) 35 (61 bytes bigger than LHarc)
ZIP (Default) 36
ZOO (Default) 41
ARC 41 (739 bytes bigger than Default ZOO)

Binary: (155722 bytes)

Time taken:

ZIP (Default) 36 secs
ZOO (Default) 45 secs
ARC 50 secs
ZIP (Deflate) 61 secs
LHarc 62 secs
ZOO (Slow mode) 90 secs

Compression (% of original size)

ZIP (Deflate) 37
LHarc 38
ZOO (Slow mode) 38 (10 bytes bigger than LHarc)
ZIP (Default) 41
ZOO (Default) 56
ARC 58

The overall ratings - taking into consideration, the time taken,
and the relative compression gained within that time (the total
averages), are as follows:

Speed Compression

The winner: ZIP (Default) 1st 3rd
#2 : ZIP (Deflate) 4th 1st
#3 : ZOO (Default) 3rd 4th
#4 : ARC 2nd 5th
#5 : LHarc 5th 2nd=
Last : ZOO (High compression method) 6th 2nd=

Versions used:

ST-ZIP v2
LHarc v2.01L
ARC v6.02
ZOO v2.14

You can use different weighting for the importance of speed
compared to size ! Of course, LHarc is the worse if time is important
as it always uses a slow but quite efficient algo.
If size is more important, on the other hand, it will be 2nd !

One thing is sure: ZIP is the best in this bechmark !

For the rest, you can interpret the result as you wish !
Personnally, I only use archives for their size (to store on
floppy, or just to gain room on my small HD) so that
speed is not really an issue but size is !

If I want to be fast, I just don't compress at all!

Yucck! It sure does. What a nasty way to cripple a machine. Is it
so darned expensive to not run 2 more address lines and give you a reasonable
64MB limit (like anyone is touching that yet, but it leaves room for
expansion). Sigh. I know, I know - since it (26) isn't a nice multiple
of 8, you have to add a slew of logic chips...but how about 28?:)

Whups! Looks like you slip an order (or so) of magnitude. The only
thing on the Falcon rated to go 50 anything, is the sound can be sampled/played
at 50_K_Hz. The chip itself has been said to run at 32MHz. AD/DA are not
likely to be clocked in the MHz range. You could broadcast your own FM station
if they were (well, maybe AM) :).

Of course, with its 96k of its own memory, the DSP could probably out
perform the CPU (special mathmatical permutation logic aside). :)

Well, when speaking about 24 and 32 bits, it was about data and not address bits: the DSP56001 has a data path of 24 bits ! (and an internal register size of 56 bits hence the name. Little game: guess what's the register size of the DSP 96002 ?)
This width difference surely poses some problems for implementing DMA or other memory accesses !

LHarc DOES have a 'fast mode' which involves simply 'storing' the files - so, I didn't bother testing it, as for archival purposes, it's use is very limited.

I know that ZOO's lack of speed has been known for a while - and I never said it was a new discovery, I was merely showing it for comparison purposes. Besides, there are always new users out there!

ZIP's compression technique is not Lh5 - it has a completely different technique - which is basically 'Implode' except it tries harder!

I assume that the 56001 can only deal with integers (i.e no floating
point), is this true?

Hello all!

I have a 4MB ST with a 105 MB hard drive. I used to backup to floppies, but as data grows it becomes tedious...

So now I am looking for a tape drive. What are the recommeded solutions (both hardware and software parts, SCSI or other, etc)? I don't need a plug and play solution per se: I know how to use the soldering iron as well as how to develop some software.

Please respond by E-mail as I usually don't read this group.

Regards,
-Roger

I have been trying to get a version of gnu emacs running on my 1040 STe with 4 meg and have not had any luck. I downloaded the MiNT files and the emacs for mint off of a.a.u.e and got all the files put in the right place, set my environment variables, and attempted to invoke emacs.

Only problem is, every setting that I use for TERM, I get same response.

It says that the setting does not support emacs as it can not position the cursor.

Anyone know what I gotta do (or what kind of termcap I gotta get) to get emacs working!!!!

swood

I believe the Falcon has a 24-bit address bus and a 32 bit data bus, while the 56001 has a 16 bit address bus, and a 24-bit data bus. The Falcon is a 32-bit computer with limited memory management.

> Motorola says the top speed the 56001 is clocked at is 33mhz, so the
>ad/da converters must be the parts clocked at 50mhz.

The adc/dac channel is driven off the DMA clock, which is driven off a sub-divided horizontal scan rate. The 525 scan line rate sub-divided by 12, 24, 48 and 96 give the 6250, 12500, 25000 and 50000 bytes per second DMA/CODEC rate. This is the same as the STE/TT.

Just passing along what I've heard...

Once again: if you don't read this group, don't ask questions in it:
it is not just a hot-line: it is a conference !

If you think it is worth asking a question, then it is worth reading
it sometimes (cause this way you may have an answer for someone else's
problem)

And by the way: never only respond by email, as someone else may
be interested. (That's the case for me on that question)

Actually, not much effort is _required_ to migrate from the 68030 to the 68040. I work for Microware Systems, the makers of OS-9 (a competitor of VxWorks), and we also support the CPU-30 and CPU-40. The operating system really doesn't need to worry much about the differences, although to optimize for the 040 you want to take advantage of its different cache architecture (we do). The compiler maker (at Microware we do our own compiler technology, Wind River has customers use third-party or other compilers) needs to be concerned with differences in the floating point hardware and, for optimum performance, instruction set changes. (The 68882, typically designed in with a 68030, does both floating point and transcendental/trig functions in hardware, while the 68040's built-in FPU only does floating point necessitating software emulation for the transcendental/trig functions.) However, in most cases the 68040 is 100% backwards compatible with the 68030, so object code need not be recompiled. The Force CPU-40 does have some different support hardware than the CPU-30, so those particular drivers would need to be modified.

>We have noticed a definite speedup using the '40s in our
>applications, but I have heard some horror stories of some
>applications running the same or slower than '30s (the math
>functions not supported by the onboard FPU and hence microcoded

>prevalent in the first ports to '40 boards (remember, a 68040
>processor board has more components, and possible problems, than
>just a 68040).

If there is lots of trigonometric code in your application you may find a 68040 to be slower than a 68030/68882 because the internal coprocessor can't directly handle the transcendentals. (The 68060 is supposed to fix this.) Other code, including normal floating point, will be faster on the 68040.

>At any rate, I don't think every C application would have to be

>a lot of those nifty games and graphics seem tightly embedded,
>don't they?)

Neither assembler nor C code should need recompilation, as long as there are
no direct trig calls. Again, however, your compiler may be able to more
highly optimize code for a 68040 than a 68030 if you _do_ recompile.

The operating system really doesn't need to worry much about the differences, although to optimize for the 040 you want to take advantage of its different cache architecture (we do). The compiler maker (at Microware we do our own compiler technology, Wind River has customers use third-party or other compilers) needs to be concerned with differences in the floating point hardware and, for optimum performance, instruction set changes. (The 68882, typically designed in with a 68030, does both floating point and transcendental/trig functions in hardware, while the 68040's built-in FPU only does floating point necessitating software emulation for the transcendental/trig functions.) However, in most cases the 68040 is 100% backwards compatible with the 68030, so object code need not be recompiled. The Force CPU-40 does have some different support hardware than the CPU-30, so those particular drivers would need to be modified.

>We have noticed a definite speedup using the '40s in our
>applications, but I have heard some horror stories of some
>applications running the same or slower than '30s (the math
>functions not supported by the onboard FPU and hence microcoded
>appear to be the culprits), but these might have been more
>prevalent in the first ports to '40 boards (remember, a 68040
>processor board has more components, and possible problems, than
>just a 68040).

If there is lots of trigonometric code in your application you may find a 68040 to be slower than a 68030/68882 because the internal coprocessor can't directly handle the transcendentals. (The 68060 is supposed to fix this.) Other code, including normal floating point, will be faster on the 68040.

>At any rate, I don't think every C application would have to be
>recoded to run on a '40, but assembler would be a different
>story and also the more an application embedded itself in the
>current hardware architecture, the more changes needed (and

>a lot of those nifty games and graphics seem tightly embedded,
>don't they?)

Neither assembler nor C code should need recompilation, as long as there are
no direct trig calls. Again, however, your compiler may be able to more
highly optimize code for a 68040 than a 68030 if you _do_ recompile.

Actually, it's more appropriate to look at the Falcon030 as being 24-bit
'off-the-shelf' so as to be as compatible with the ST as possible. From
everything that's been said on GEnie, expansion to full 32-bit isn't all
that difficult to do. The Falcon030 still has a 32-bit bus and all, so
I don't really even think it's appropriate to imply it's 24-bit in any
way.

I haven't seen any mention of this bug before, bummer...

By the way, since the .95 release, there have been 3 more patches sent out -
the one I mentioned above, and two more bringing it to version 0.96,
patch level 1. Dunno when a binary for these will be made available.

Not to flame anyone, but I don't agree.
If someone doesn't read a group they may have good reasons for not doing
so. How could anyone else know? Even if they were just lazy, why shouldn't
they be allowed to ask an occasional question? Nobody is obliged to
answer them anyway.

And considering the large flow of news, nobody could be expected
to participate in more than a few newsgroups. Still they may very well
come upon questions that can't be answered in their native groups.
So why not ask about it in the appropriate group and use the huge
source of knowledge that Usenet is?

Zoo says 'default' -- but it has a higher compression option too!
It takes longer, but does a better job. This tradeoff should be
taken into account.

Zoo is a lot more user-friendly than the other archivers, too. :)

Besides, to function with an atari getting stuff from the net, you
really need *all* archivers installed on your system, or at least
on your net-connected (UNIX) system so you can unpack and repack
the archives before downloading them.

ZOO is only user-friendly if you are being pointless and running UNIX on an ST. RUnning it from standard GEM, you can't re-direct it's output, which is a real nuisance! ZOO, ARC, and LHarc can all be told where to put their extracted files/archived files once they have extracted/archived them!

I have shown the 'High compression' method of ZOO. It takes a LONG time - and gets about the same compression as Lh5 (LHarc), it's slow speed is it's only MAJOR draw-back, optimising the code a bit, and speeding up the routines would make it quite usable! (Also adding a re-direction for the GEM users, the numbers of which seem to be very small in an Atari message area - seems quite illogical!)

ZOO's compression isn't bad as seen here:

Compression (% of original size)

ZIP (Deflate) 37
LHarc 38
ZOO (Slow mode) 38 (10 bytes bigger than LHarc)
ZIP (Default) 41
ZOO (Default) 56
ARC 58

10-bytes difference is not much - especially as the file-size is always rounded up to the nearest 1k, as more than one program can't occupy the same sector on the disk - so GEM reserves it for that program/file, and so a 689 byte file, is actually 1k big (1024 bytes).

Unfortunately - this good compression, loses out on the speed: (Note 'Slow Mode' is the 'High Compression' mode of ZOO)

Time taken:

ZIP (Default) 36 secs
ZOO (Default) 45 secs
ARC 50 secs
ZIP (Deflate) 61 secs
LHarc 62 secs
ZOO (Slow mode) 90 secs

it took 28 seconds longer than LHarc to compress to virtually the same filesize. the file it was compressing was only 150k. Zip's Deflate mode was only 1-second quicker than LHarc, but it got almost 2% better compression! (No biggy, but it's an improvement!)

At least to me, compression is the important thing. It may take a
-little- longer to compress or decompress a file, but when you are
downloading it long distance or off one of the services (like GEnie) then
the compression saves you some money (particularly over the long run).

From: plate@cdsmn.mn.org
Message-ID: <Btyy0L.E3M@cdsmn.mn.org>
Source record: 42927

I have two printers: Okidata 182 Turbo and HP Paintjet (on loan to me).
I have had the hardest time doing anything meaningful with these printers
as far a graphics output etc. I am especially frustrated about the
PaintJet because I know it is capable of some incredible output given
the correct software.

First: GDOS/FontGDOS
I have installed FontGDOS, but still haven't any real clue on what to do with
it! I assume that in order to make use of it, I need a program that is
specifically written to use GDOS. Is this the correct assumption? Then I
guess I would have to start collecting fonts? I have read the "GDOS.DOC"
and most everything else I can find on the subject, but I'm missing something
somewhere. Maybe I need a demo.

Crackart:
Any printer drivers available? I love this program and need to get on the
stick and send those gentlemen some Deutch Marks!

Regards,
Doug Plate Sr. <-(Note the new addition to the name?)

I just wish that there was an ARJ compressor for the ST, the UNARJ leaves
the others for dead, it's compression is better than everything else,
and it's speed it only very slightly slower than the fastest one!
Any of you people in .tech reading this feel like writing one? :-)

some results from a test I did a while ago....

The test was on : 34 files, 231065 bytes uncompressed

Method	Size compressed	Time to decompress
LZH	109900 bytes	38.5 sec
LZH v5	88268	43.9
ARC	129045	39.5
ZIP	110628	25.2
ZOO	89462	40.7
ARJ	87812	26.4

3376. Need fast image conversion algorithm.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-03 06:21:48 UTC
From: timg@ccwf.cc.utexas.edu
Message-ID: <79002@ut-emx.uucp>
Source record: 42929

Hi,

Does anyone have a fast algorithm (or some code) to transform
a packed color image into the appropriate number of color planes?
The packed format for a 4-bit image looks like this:

byte

1 2 3

XXXX XXXX XXXX XXXX XXXX XXXX ....

1 2 3 4 5 6

pixel

Ghostscript produces color images in the above format (sort of, I
actually have to sample an 8-bit image). For portability, I need to
first convert this to the standard GEM format of four color planes, and
then transform it again to the machine specific format. There is a vdi
routine for the last transformation, but I have to do the first myself.
All these transformations hog time and memory, so I would like to make
the one I have to write as fast as possible.

The GS screen driver is written in C, but assembly routines would be OK.
It would also be nice if the algorithm could handle 2, 4, 8, 16 and 32
bit color.

Maybe some hot game hacker could code this up for me to show doubters
that there is still a useful place in the world for his kind of
programming (just wishful thinking :-); or maybe I should announce
a programming contest, yeah, that's it. The winner gets a free copy
of Ghostscript!

Thanks,

Tim Gallivan

3378. downloads with Uniterm (kermit)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-03 09:31:09 UTC
From: rosenkra@convex.com
Message-ID: <1992Sep03.093109.16255@convex.com>
Source record: 42930

i am using uniterm 2.0e on a mega ST4 (TOS 1.2) with a 9600 baud modem (AMT STAR 9642e).

downloading file with kermit protocol from a unix system is about 4-5x slower than uploading. i am using 1000 byte packets on both ends for both send and recv. why the big difference? is there any way to "fix" this (i am using default buffer sizes in uniterm). uploading appears to be about 3-4x faster than uploading at 2400 baud. i think this is a V.42bis modem (i am using the factory defaults which i think is AT\N6, ie V.42 with fallback to MNP with fallback to normal, and AT\Q3, ie RTS/CTS). i think i am using C-Kermit 4E70 on the unix side. the serial line is the phone company.

thanx

> Please respond by E-mail as I usually don't read this group.

SM> Once again: if you don't read this group, don't ask questions in it:
SM> it is not just a hot-line: it is a conference !

It depends upon the question, doesn't it? A FAQ-like question should
normally *not* followed-up unless it happens repeatedly. The only
gaffe that I see in Roger's posting was that he did not offer to
summarize in case others might be interested.

SM> If you think it is worth asking a question, then it is worth reading
SM> it sometimes (cause this way you may have an answer for someone else's
SM> problem)

The person must have been reading some; otherwise he never would have
posted to this newsgroup. And if one hasn't read a newsgroup in
awhile then either all the interesting messages have expired and/or
there are 500 some messages waiting to be read.

SM> And by the way: never only respond by email, as someone else may
SM> be interested. (That's the case for me on that question)

True, it is an interesting question (I wish my HD was big enough to
require a tape backup ;-( ), but if one is not *that* familiar with
this newsgroup, then one would have difficulty in judging the
importance.

Discussions may go one both publicly (news) and/or privately (e-mail).
I have no qualms with either. By the way, your followup (like mine)
lacks technical content. That's why I redirected followups to
comp.sys.atari.st!

3380. GNU make 3.62 at atari.archive

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-03 15:07:34 UTC
From: as327@cleveland.Freenet.Edu
Message-ID: <1859nmINNmuh@usenet.INS.CWRU.Edu>
Source record: 42933

I just downloaded version 3.62 of GNU make and there seems to be a problem with the executable .ttp file. I tried to execute it both under plain Gulam and under Bash 1.05 in MiNT. The results were the same - it said that "c:\bin\make.ttp: file not found". This is absurd because if I do an 'ls' command on that file, it IS there. If I specified the full pathname "c:\bin\make.ttp", I get either the "file not found" rubbish or a -39 return code (under Gulam) or "memory exhausted". Anyone have any ideas? Maybe the 'make-362.zoo' file needs to be uploaded again. Meanwhile, I suppose I'll go back to make 3.60 (which I don't look forward to, since in the middle of building big source directories like the GNU library, it aborts on a "virtual memory exhausted" error and needs to be re-started).

Thanks.

P.S. Since Frank Ridderbusch did this port, I tried sending this to him first, but it bounced.

It uses 24/48/56 bit fixed point arithmetic(sp?).
There is a fast floating point lib. available if a S/N of 144 dB (24bit) to
350 dB (56 bit) isn't enough.

You're right: if you've got the 18.58 release, the elisp code is
even included. It is part of the machine specific files like
atari.el (for the cursor key and such) and is called msdos.el
or msstuff.el or something like that !

If you don't have 18.58, try to get it (it was in a.a /atari/new
but I can't remember the name): it is much easier to install
and is a bit more complete.

>Hi, has anybody got a copy of the full version of the MACEXCHANGER
>ShareWare program ? What I'd like to know is how successfully does it c

there's a simple trick to make a disk readable on spectre and Mac. I don't
have a spectre but it's supposed to work:
start the Program 'convert files' and insert disk (on either hardware).
When the format box appears, it suggests 800k Mac or 720k MS-DOS. If you
click on the disk Symbol in the box you may suddenly format
720k Mac !!

This format is supposedly recognised by both hardwares. In sys7 this Hack
still works, if you edit the rsc and make the disk-symbol selectable again
(can't remember the Mac-term for it).

Kai.

>--

Actually there is.

I guess that you have the MiNT version of emacs. There is another port, based
on the most recent version (18.58) of emacs.

Included in this is a little elisp-package which will automatically remove the
^M characters while visiting a normal atari file. They are of course reinserted
before the file is saved.

I can't remember the path on atari.archive right now, but try checking the
gnustuff directory and/or the editor directory. This little package is worth
the entire download.

Don't forget that the appearance of the ^M characters is actually a feature.
One of the advantages of emacs is the ability to handle arbitrary
control-characters as ordinary characters that can be searched and replaced and
whatever. Then if the characters is not desired, it is small trouble to hook up
functions to delete/reinsert them when loading/saving the file.

3395. Re: LASER C PRINTING

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-04 14:53:36 UTC
From: max@neumann.cba.csuohio.edu
Message-ID: <1992Sep4.145336.4676@news.csuohio.edu>
Source record: 42997

From what I can tell, Atari and LASER C run things this way:

LEVEL OF COMMUNICATION IMPLEMENTATION TYPICAL CALLS
Device BIOS Bconin, Bconout
File descriptor GEMDOS Fopen, Fread, Fwrite, Cconin, Cconout
Stream LASER C fopen, fread, fwrite, printf, fprintf

Each higher level uses the previous level to accomplish their tasks.
For example, printf calls Fwrite, (yes, even for screen output!), and
Fwrite within the operating system calls Bconout at some point.

An array of 20 _iob structures are standard for LASER C programs, which
are used for the fread, fwrite, printf, etc. The first three are
already used when your program runs, much like UNIX does things. These
are _iob[0], _iob[1], and _iob[2], which are structures whose addresses
are stdin, stdout, and stderr, and represent buffered file IO, called
streams.

In UNIX, the first three _iob structures use file descriptors 0, 1, and
2. But in LASER C, it is 0, 1, and 1. Writing to stderr is really the
same as stdout. In UNIX, programs know to write to any one of three files
whose descriptors are 0, 1, or 2. But in Atari, there is only 0 and 1.

Even if you can manage to Fdup the console output and change the
association of stderr to it, programs executed with this in place won't
care about what you did, because only file descriptors 0 and 1 have
significance.

Furthermore, in UNIX, opening a file results in file descriptor 3, the
next consecutive number, being used, wherease in Atari, it is number 6.
(Let me use "fd" to mean file descriptor.) This is because Atari is
different than UNIX as far as standard devices is concerned. UNIX uses
your /dev/tty?? as your single device. Atari likewise has the console input
and output like UNIX but also has a serial port (fd 2), printer port (fd 3),
and two other devices open (fd 4 and fd 5) when your program begins.

LASER C has no such thing as stdprt, that is, a pre-opened stream
connected with the printer. However, the printer device is ready and has
fd 3, so you can simply associate a stream with it as follows:

```
#include <stdio.h>

FILE *stdprt;

main ()
{
stdprt = fdopen (3, "w"); /* make a stream for the printer */
```

```
fprintf (stdprt, "This goes to the printer");

....
}
```

Thanks for all the responses. I downloaded 'gmake362.zoo' from the 'new' subdirectory. The readme file said something to the effect of Frank doing some weird code which only worked with the RCS setup on his machine and this new version should work on everyone's machine. Well, I don't know about that, but it works on mine now.

By the way, is there no one to maintain atari.archive now? It seems to me that this and other similar problems would not happen if there were. Too bad I'm not a Michigan student ...

It shouldn't really be a problem to write an elisp program that removes
^M characters when loading a file, and adds them at the end each line
when saving.

> care about what you did, because only file descriptors 0 and 1 have
> significance.

A clarification:

That's true for Laser C (with the default Laser C library) but not necessarily for other compilers/libraries. For example, the MiNT library and gcc library use handle 2 for stderr; they do this by checking to see if handle 2 is pointing at a terminal of some kind (by default this is true, since GEMDOS sets handle 2 to point at the serial port). If it is, then it is redirected to point at the console. If it is not (if someone has pointed handle 2 at a file, for example) it's left alone.

For this reason, programs should not assume anything about handle 2 (e.g. it's better not to assume that it's pointing to the serial port). If you want to open the serial port, use the file name "AUX:".

3403. How do I replace an existing GemDos routine or add a new one?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-06 07:47:46 UTC
From: mforget@ersys.edmonton.ab.ca
Message-ID: <B76NqB1w165w@ersys.edmonton.ab.ca>
Source record: 43006

Hi,

Could someone tell me exactly how to replace an existing GemDos function? I can assume that the first step would be to write the routine in the form of a program and then have the program terminate and stay resident (ptermres). What I do not know how to do is replace the routine.

I have also seen programs (MiNT, for example) that add new system calls. How is this done? Is it simillar to the method for replacing calls?

The reason I am asking about this is I am thinking about writing an ANSI emulator, and I would like to see if it is feasible to write it in the form of a TSR that any program could use simply by calling the appropriate routines.

For example, the program in use could take the input from the serial port, and if it is in ANSI mode, it could pass all output to the screen through a new system call that would catch the escape sequences and process them appropriately.

To me, this would be better than an ANSI emulator that is only available in one terminal program.

Any help would be appreciated.

3404. RS232 port, Rsconf() is that all i need?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-06 08:55:47 UTC
From: wilsont@holonet.net
Message-ID: <Bu5FGz.M80@iat.holonet.net>
Source record: 43007

as sugguested I bought some recent Atari Explorers, and read the articles
on serial port programming.

Well, i typed in the first "very dumb terminal program"
and added this line:
Rsconf(4,0,8,0,-1,-1,-1);

which should be 2400 baud no parity,no handshaking, 1 stop bit.

however, my modem does not respond with an RD light up.
I changed the Cauxout(c) to Bconout(1,c), that made the RD light up,
but also the CD as well!

what am I missing?

any help would be apreciated! (source code would be cool!)

Compiled with Sozobon 1.33i, standard Dlibs.
I ran it from Gulam, and the desktop.

BTW, gulam likes to echo the characters to the screen from a Cconin() why?

thanks!

Timothy--

3405. WAACE AtariFest 92' October 10 & 11

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-06 12:18:54 UTC

Message-ID: <1992Sep6.121854.9264@access.digex.com>
Source record: 43019

WAACE AtariFest 92

The Washington Area Atari Computer Enthusiasts will sponsor W.A.A.C.E. AtariFest 1992 on October 10 and 11. The show will again be staged at the Sheraton Reston Hotel in Reston, VA. Show hours will be from 10 am to 6 pm on both days. In addition to the shopping bargains available from over thirty vendors there will be a full round of demonstrations, tutorials, and seminars. A banquet on Saturday evening will feature a special speaker on Atari matters and Current Notes Magazine's "Author of the Year" award. Special mixers will cap off the evening's festivities. The 1990 and 1991 editions of the show attracted approximately 2000 visitors.

The Sheraton Reston Hotel is a spacious, attractive facility located in a parklike setting near Washington, DC. The hotel is offering a special room rate of $59 per night plus tax to 'Fest attendees. Call 1-800-392-ROOM or 703- 620-9000 for reservations. Be sure to mention W.A.A.C.E. AtariFest '92. The number of rooms available at this special rate is limited, so make your reservations early. The price that W.A.A.C.E. will have to pay for the exhibit space is directly tied to the number of hotel rooms that are rented out.

If you have any expectation at all of attending the event we would like you to reserve a room for Friday and Saturday nights. Immediately following the 1991 show Charles F. Johnson of Codehead Technologies announced that W.A.A.C.E. '91 was the most profitable outing that they had ever had, anywhere. For eight years W.A.A.C.E. has provided a complete Atari experience. 1992 promises to be in that same tradition. For additional information please contact: Russ Brown via GEnie (R.Brown127), by voice number - (703) 803-6126 (Please do not call after 10 PM EDT), and/or Email to jhurwitz@access.digex.com

3406. T10 as a slave to the MegaSTe

Newsgroup: comp.sys.atari.st.tech

OK, folks, just wondered before I begin this project if it was
possible. I have an old T10 terminal here that I would like to hook up
to the extra serial port of my MegaSTe and use a dumb terminal into it....
I will of course use MiNT and I have the termcap for a T10 so thats not a
problem. I wanted to know if anyone has done this sorta thing, and if it
is indeed possible? For instance the T10 could be used as a vi editor,
cli for small jobs even for compiling freeing the ST to do GEM stuff?
Sound plausible? Any suggestions?

3407. C code to have different font

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-06 18:16:55 UTC
From: BING_SIN@bdt.COM
Message-ID: <1992Sep6.181655.19938@bdt.com>
Source record: 43012

Can someone tell me or send me some source code in Laser C to replace the system font to some other font just inside my program. There was a program which create font and you have a choice of saving your font file in either *.FED, *.O, and *.C. When it saved as a .C source code file, it does not have any code in there to manipulate the font and the program does not come with any doc at all.

There is a program call ANSITerm from Two Worlds Software, which replace the system font with it's own. I wonder how does they do this?

Please reply, I need a lot of help on this.

Hello...yes, all HAIL. Greg Carter is BACK...

WELL, FIRST OF ALL, Rsconf() only has 6 parameters.

Try Rsconf(4,0,UCR,-1,-1,-1);

The UCR is a bitmap that controls the various things your looking for
in transmission format, suich as 8N1. Unfortunately, since I don't carry
said bitmap with me everywhere I go, I can't tell you what the individual
bits do.

I will post my serial port goodies in a short while.

I'm am unable to compile the Motorola 6809 cross-assembler using
the H&S Sozobon C compiler due to two errors:

```
error in as.h (124): pointer type not allowed
error in ffwd.c (10): pointer type not allowed
2 errors
```

The code for as.h (lines 123 and 124) is:

```
FILE *Objfil =0; /* object file's file descriptor*/
char Obj_name[] = {" "};
```

And the code for ffwd.c (lines 9 and 10) is:

```
int Forward =0; /* temp file's file descriptor */
char Fwd_name[] = { "Fwd_refs" } ;
```

I'm just starting learn how to program in C and could use any
suggestions that you might have.

Given this little piece of code, I would just suggest to remove
the { and the } in lines 124 and 10 !

At least, these are syntax errors !

There is a recent discussion about tape drives for the Atari. Because of
the high list price I was lloking for an alternative. At the Atari Fair in
Dusseldorf I found it. It was a pitty they where not yet in production
but I ordered one anyway. It is a video streamer. It uses a standard VCR
which has to be equiped with a scart connector as backup device. It backups
600 Mb on a E240 tape. So about 2.5 Mb per minute. It can make image backups
as well as file backups and restores visa versa. I don't have the address of
the German company on hand. If anyone wants some more info, drop me a mail.

BTW the listprice of the device, which connects on the parallel port, is about
DM249,- which is at the current ratio about $180,-

Greetings from the Netherlands.

>

That's certainly feasible, but there are better ways to do it than replacing (or adding new) GEMDOS calls, I think. I would set up a cookie in the cookie jar, say with the name 'ANSI' and with a pointer to a function table as its value. Programs which want to use the ANSI functions would look up the cookie, get the table of functions from the cookie, and then jump through the table to the appropriate functions.

(I think this is better than trying to add/replace GEMDOS calls because it doesn't add any overhead on the trap #1 vector.)

Under MiNT (and probably under MultiTOS) you could write your ANSI emulator as a device driver, and have it install a device like U:\DEV\ANSI; programs could then open this device and use it just like any other. It probably wouldn't be too hard to make your program work either as a device driver (if MiNT is active) or as a 'cookie-driven' TSR; just make the functions in the cookie's function tables the same as the functions needed for a MiNT device.

Yes, I've been using a little utility called HC24_H12.PRG which
I downloaded from atari archive at University of Michigan. It is originally
by R. Hoh and has been modified by Ulf RIMKUS (for PURE C). This gives a
dump in the HORIZONTAL (portrait) mode. There is a companion program called
HC24_V??.PRG if you want vertical 24-pin dumps. The C-code accompanies the
program HC24_H12.PRG and I had no difficulty in compiling it under MWC and
making some (very minor) mods (like removing the RESET-Printer command at
the start which produced an annoying accompanying Form Feed on my NEC P2200
so that I could not choose where on the page to have the (horizontal) dump).

I discovered that loading HC24_H12 deprives your available RAM of
about 32,260 bytes (although the program itself compiles to about 1.2
kbytes only).

Cheers, W. Alan B. Evans

Hi again. ok you tech guys...
how do i get sound samples out of my ST?
is optimized C fast enough to handle this job?

I've looked in my TOS book, but only the PSG s there, and it doesn't seem to
have a way to control the speaker directly.
I also looked at noisetra.s, (68k code for noisetracker), but it seems not
a single standard call is used (therefore i couldn't reference it)

Thanks for helping me with the screen memory... i found Setscreen...just what
i needed!

books, code, ftp site would be helpful!

3418. problems w/ 2 SCSI drives on ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-08 06:34:54 UTC
From: kruel@wpcst1.phys-chemie.uni-wuerzburg.dbp.de
Message-ID: <H._49DdC_yXeQ@wpcst1.phys-chemie.uni-wuerzburg.dbp.de>
Source record: 43026

Dear netters,

I have a little problem with two SCSI discs on my host adaptor:
they won't work together with addresses 0 and 1.

Some details: The drives (a ST 157N and ST 296N) are connected to a
GE-soft adaptor. The first is configured as SCSI device 0, the second
as device 1. The software is from Digital Systems Krueger (Version
3.2). The problem: write access to the first device (the ST157N)
crashes the FAT and DIR.

Everything works fine if:
- the drives are used solely;
- the second drive is configured as #2 or higher.

So I can work with it, but I'm curious: What may be wrong ?

Is it absolutely necessary to remove the resistor packs ? If so,
which drive ? The physically last or the logically last one (which is
different in that case) ?

Also:

I need to reformat the ST 296N on a low level, since it stems from a
PC, where it was formatted with interleave 2.

Is there some PD/Shareware/commercial package out to do that for me ?
I checked AHDI5 but it doesn't. I heard about "SCSI-Tools" from
Hard&Soft in Castrop-Rauxel, but I don't know if the DM 149.- (~ $100) are
worth it ? Any experiences ?

Thanks for any hint,
Thomas.

Hi.

I have recently ported Eric Young's DES Library to the Atari. The
port went without problems so far, only des(1) keeps making trouble.
The library can be obtained via

ftp.uni-kl.de:pub/atari/incoming/des-src.zoo Library sources
ftp.uni-kl.de:pub/atari/incoming/des-bin.zoo .olb file

The documentation is somewhat sparse but useful nontheless. If you
don't know what ECB or CBC means, then this library is probably not
for you.

The library originated in Australia, i.e., outside the USA, and is
therefore not restricted to USA-only redistribution. USA residents
might not be able to get a copy legally.

The library was compiled using GCC 2.1, and MiNT 0.94/Libraries PL 20.
You'll need GNU make to make the library, otherwise you'll have to
fiddle with the makefile.

Bug reports to me (neuhaus@informatik.uni-kl.de). I will forward them
to Eric (eay@psych.psy.uq.oz.au) if necessary.

Have fun.

I have a similar problem with a Seagate ST125N drive - I can't access/
low-level format or anything the drive - The drive light just flashes a lot.
The problem is that this drive is BRAND NEW (never used although out of the
guarantee period). I opened up the drive and checked it - the platters spinn
correctly but the heads just goes up and down the platters - as if looking
for something but not finding anything.

Could anybody shed some light on the problem ?

Thanks David.

Situation.
I have a 520STFM (2.5 meg). I will almost definately buy a Falcon.
I might also be given a PC XT from a friend. (I don't really like PC's!)

Question
If I get a SCSI drive, either in the Falcon or more likely, in the PC, can I
get both computers (or even all three!) to run from the same drive?

Thanks,
Phil

3422. can't get gdb to work

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-08 13:43:04 UTC
From: svleest@jobim.crhc.uiuc.edu
Message-ID: <18ial9INNqi9@roundup.crhc.uiuc.edu>
Source record: 43024

I am having problems getting gdb, the GNU debugger, to work.
When I compile a program for debugging and then use sym-ld to
build the symbol table, all is fine. I then run gdb. I can use
"info function" to list all the functions in my test file.
HOWEVER, if I then try to run the program, it exits IMMEDIATELY, with
the message:

Program exitted with status = -32

This happens regardless of how simple or complex test.prg is.
What am I doing wrong? I have noticed that if I use examine
to look at the data, it reports everything is 0. Is this because
gdb does not actually load the program until you command it to
"run", or is this part of my problem? I have the following versions:

gdb 2.6 Patchlevel 18
gcc 1.40 Patchlevel 2
gcc-ld and sym-ld Patchlevel 27
gulam cli

I used the following command sequence:

```
>gcc -c -g test.c
>gcc -o test.prg test.o
>sym_ld -r -o test.sym crt0.o test.o -l gnu
>gdb -e test.prg -s test.sym
*run
```

(where ">" is the gulam prompt, and "*" is the gdb prompt) and I
get the error described above.

Any help would be greatly appreciated!

By and large, compression IS the important thing. How often do you compress/decompress any given archive? Not ALL that often, I'd expect. If you actually USE a program enough times to make it worth downloading, it's certainly going to be enough times to obscure the extra 10 seconds it might take to decompress the archive.

And when MANY users are using a given archive, it's better to have it shorter rather than longer. People may be paying money for each K downloaded, or they may be using a slow line to transmit data, and in these cases, the inferior size would outweigh any savings in time from a faster decompress...

You might save 20 seconds, and the size might degrade by 60K on a large archive.

But guess what? At 2400 baud, it takes 2-3 minutes to download that extra 60K. Hmmmm... The net effect looks like a LOSS of 2 minutes to me...

Plus, you may wind up PAYING for that extra 60K. Save 20 seconds, but pay $3 for it. Your time would have to be worth $540 per hour in order to save money this way...

In short, the higher the compression, the better. If it costs SOME time, so be it. It's probably worth it...

3424. "fast" sprites in C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-08 16:06:39 UTC
From: klassa@aurs01.UUCP
Message-ID: <61138@aurs01.UUCP>
Source record: 43032

Hi All-

I've attempted, on a couple of occasions, to write silly little games for my own amusement. What I always run into, though, is terrible, terrible performance when I try to put objects on the screen and animate them. My mind keeps going back to that ST classic "Megaroids," which was claimed to have been written in C (although I'm not positive that they didn't use assembler in there somewhere). How do you, the readers of comp.sys.atari.st.tech, get good performance when doing sprites? *Must* I use assembler, or can it be done in C? (My problem is that I don't know assembler...) On a related topic, I remember a long discussion between (I think) Dave Baggett and somebody else, on the topic of double-buffering & handling it during vbl and so on... Is double-buffering pretty much the only way to give animated games that "smooth" look? If so, I would imagine that assembly is required there, too...

Thanks for any and all input!
John

P.S. How do y'all handle keyboard input? i.e. How can I detect when multiple keys are in the down position? How can I turn every key into a "shift-like" key, so that the player can hold it down as long as he/she wants to without it going into repeat mode, etc.?

Thanks again!

a) the Seagate ROMS (296N anyway) have a problem... You must set all drives
in a system to an EVEN id to prevent problems, I've combined 296n(s) using IDs
of 0,2 and 2,4 with no problems. I got "the cure" via Tech. Info. at ICD.

b) the Seagate 296n drives I use are MUCH faster at 2:1 interleave. I'd
reccomend you leave the interleave at 2:1 for now. If you want to test 1:1,
be prepared to change it back! Again... this is a ROM problem, but I know of
an update (by Seagate) to fix this. Don't see any socketed ROMs on my 296n
though... so I live w/o the fix.

Hope this helps!
jc

Sure, assembly is necessary if you realy want to get the speed of current games. But, you can do games without !

Double buffering is available from about any language (XBIOS)
And for fast animated sprites, you HAVE to do 'precomputing', that is preparing the data so that wherever your sprite should appear, it just has to be put there without having anything more to compute (bit shifting,...).

But, sure this precise part of sprite display should be written in assembler, as you sure can get a speed improvement of about 2 to

much more (depending on the compiler and on you).

In general, high speed can be achieved with a little of assembler
on the critical points and a lot of C for the rest. Of course
all assembly can give you a bit mor speed (helpful to
get the real 'video-game' feeling, I think)

Good day.

I have downloaded the UNIX release for PGP 2.0 from ghost.unimi.it and placed it in ftp.uni-kl.de:pub/atari/incoming. I tested compilation and basic functionality on a SUN Sparcstation, and the docs say that it should also compile on an Atari. I have not tested that yet.

The files are pgp20src.zoo (for MSDOS-like systems) and pgp-2.0.tar.Z (for Unices). The archives contain exactly the same files; just the names are different.

Please note that this software originated outside the USA, so you might not legally be able to import it. If anybody is interested in the docs, I can mail them some 150K bytes of ASCII text. Here is the blurb:

PGP (Pretty Good Privacy) ver 2.0 - RSA public-key encryption freeware for MSDOS, protects E-mail. Lets you communicate securely with people you've never met, with no secure channels needed for prior exchange of keys. Well featured and fast! Excellent user documentation.

PGP has sophisticated key management, an RSA/conventional hybrid encryption scheme, message digests for digital signatures, data compression before encryption, and good ergonomic design. Source code is free.

Filenames: pgp20.zip (executable and manuals), pgp20src.zip (sources)
Keywords: PGP, Pretty Good Privacy, RSA, public key, encryption, privacy, authentication, signatures, email

Yes, it is absolutely necessary that you remove the terminating resistor
packs on all but the last physical drive in the SCSI chain.

YES. According to specs of SCSI drives, you should only terminate
both sides of the bus. So in your case that would be the interface
and the last physical drive. The logical drive does not matter. On the
other hand. When connecting a second ST157N to my TT there is a all
different story. Ask me if anyone wants more details.

Marcel.

Date: 1992-09-09 16:15:43 UTC
From: avgroeni@cs.ruu.nl
Message-ID: <1992Sep9.161543.4573@cs.ruu.nl>
Source record: 42792

We had a discussion on the news about this earlier, but now that
an entirely new version of the operating system is to come out soon,
I would like to repeat this:

Atari should introduce the WM_NEWTOP message in the multi tasking
system (if they haven't already). Someone at Atari, as I suppose it
went, misunderstood the potential meaning of this message: you're
supposed to get it when ANY window was topped; not by the user
(by clicking on the window), but by wind_set(WF_TOP). Also, it is
assumed that the contents of a window do not change with its status,
be this background/foreground or changing size. Example: in new TOSes
when you make a window bigger, you will only get redraw messages for
the parts that weren't visible already. I think this is WRONG.
(Correct me if *I* am.)

3435. Using new fonts with Timeworks _2_?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-09 16:21:10 UTC
From: naffara@crc.ac.uk
Message-ID: <1992Sep9.162110.10155@crc.ac.uk>
Source record: 43038
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have been told that to include new fonts in Timeworks 2, all you need to do is change the assign.sys file and run fontwid.app. They said the new fonts will have the extension .fnt (which they do) but the font files already there have some other ending. (I forget exactly what).

What should I do?

I have a program from a coverdisk called assassin, which is supposed to create a new assign.sys file for you easily. It probably would but it only wants files ending in fnt so presumably in won't include the original ones (which I want).

Why is nothing ever simple?

Phil
(E-mail naffara@uk.ac.crc)

|> of Ghostscript!

Well the naive algorithm involves a lot of shifts which are slow
on a vanilla 68k. So (off the top of my head) here is an addition based
solution for the 4-bit case (for speed you always need to specialize, ie
you need separate code for the 2, 8, 16,.. bit cases):

*
* Entry:
* d7 #pixels/16
* a4 address of source pixels
* a0 destination for plane 0
* a1 destination for plane 1
* a2 destination for plane 2
* a3 destination for plane 3
*
* Exit:
* d0-d7/a0-a5 trashed
*

next_block:
moveq #3,d6 ; 4 words for 16 pixels
next_word:
move.w (a4)+,d4 ; get 4 pixels
moveq #3,d5 ; 4 pixels/word
next_pixel:
add.w d4,d4 ; Addition magick
addx.w d0,d0
add.w d4,d4
addx.w d1,d1
add.w d4,d4
addx.w d2,d2
add.w d4,d4
```

```
addx.w d3,d3
dbra d5,next_pixel
dbra d6,next_word
move.w d0,(a0)+ ; store 1 word of each bit plane
move.w d1,(a1)+
move.w d2,(a2)+
move.w d3,(a3)+
dbra d7,next_block
```

To call it from C you will need some extra code at the top & bottom to save/restore regs & pull the arguments from the stack but this depends on the calling conventions of your compiler.
Note that it assumes you have a multiple of 16 pixels per line so that you can have bit planes that have a whole number of words per line.

If this you too slow you can unwind the innermost loop(s). If you intend to run it on a 68030 (TT/Falcon) unwind only the innermost loop otherwise you will have a lot of cache misses (main loop would then be > 128 bytes).

>an update (by Seagate) to fix this. Don't see any socketed ROMs on my 296n
>though... so I live w/o the fix.

i didn't know about the EVEN bit. i do know that the 296N can't be
formatted to 1:1, but that is only from trying. i didn't know why. i have
a quantum 105 on ID 0 with 1:1, and the 296 (also dying) on ID 1 (i.e odd).
There doesn't seem to be any problems (apart from the usual sense $11 errors
that i am getting occasionaly anyway, regardless of any setup).
i would appreciate if you could pass me some info on the ROM fix. i'd
like to try it, seeing as it's on its last legs anyway.

Didn't Michtron have a similar device a few years back?? It seems to me
I remember such a device. There are a cartridge which pluged into the
cartridge port with two cables at the other end that pluged into your
vcr. If I remember it was slow and there was a limit as to how big a
file would copy to the video tape.

There is also a U.S. product (well at least I think it's from the U.S. :)
called DVT VCR which has been out for a _long_ time which allows hard
drive backup to VHS videocassette. I think it gives something like 20 megs
per hour or so. Perhaps videocassette recorders are less common in Europe
and so such a device is a new item there -- I know that DVT VCR has been
sold in the U.S. probably since hard drives really became a big item for
STs.

Oh, you mentioned a SCART connector, that is what most European video
equipment is capable of using, right? The DVT VCR is for U.S. video stuff
and so has two RCA-type jacks, one to plug into the VCR's video input, one
to the audio input.

Oops, well now that I think about it perhaps there is one input connector and one output connector (makes sense that the information needs to go both ways, eh :-). Oh, also I forgot to say that the price of DVT VCR is under US$100, perhaps US$79 or so.

Cheers,

Actually this is not quite true. In most cases there is no need to
remove terminators, only if you have two similar drives. That
requirement was from the days of SASI. Sometimes removing terminators
may even course problems.

I have two drives in my Unix PC here at work and in Mega ST at home
and both have terminator resistors there and no problems.

Morning.. I was just wondering, in some demos and other programs, they have very fast image or graphic manipulation. For example, magnification. What sort of algorythim would you use for realtime zooming in on a block of the screen? Thanks..

3443. 1040st floppy stopped-whats wrong?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-10 22:46:03 UTC
From: bldaniel@unccsun.uncc.edu
Message-ID: <1992Sep10.224603.25703@ctr.columbia.edu>
Source record: 42797

I have a vintage 1040st which has been a faithful friend for
many years. A few days ago, when I turned it on I noticed
that the floppy sounded strange. The system was obviously
not booting up either.

To my dismay, I discovered that the spindle of the floppy
drive was no longer turning. The head positioning motor
was working ok, and the drive light was on, but no spin.

All drive cables are connected firmly and seem ok.
Rotating the spindle manually turned it (not stuck)
but did not seem to have any helpful effect.

The system boots up fine from the external HD.

Am I looking at a bad drive? A bad controller? A bad PS?
Or some other bad dream?

Thanks in advance,
Brian

Does such a peripheral exist which could be connected in the serial port
(or any other std port) and used with tar (for example)
This would permit to use it on PC, Atari, Unix, and so on (no driver
needed)

Message-ID: <2421@devnull.mpd.tandem.com>
Source record: 42799
Cross-posted to: comp.sys.atari.8bit,comp.sys.atari.st,comp.sys.atari.st.tech

-=< MEETING ANNOUNCEMENT >=-

AUSTIN ATARI COMPUTER ENTHUSIASTS (AACE)

WHEN: Saturday, 12 Sep 92, 1400 - 1700

WHERE: Bethany United Methodist Church in Anderson Mill
(on Anderson Mill Road just southwest of US-183 intersection)
Bethel Building, Room 5

WHY: Presentation by Tim Gallivan

If you are an Atarian in the Austin area, you don't want to miss this one! Tim Gallivan, a Postdoctoral Fellow in theoretical physics at UT, will be giving us an opportunity to see an Atari ST do things many of us were unaware were even possible. Tim's machine started life as a 520STf, but now sports 4 MB and an AT case with DEC LK201 keyboard. The foreign case also houses his two floppies and 85 MB hard drive. Tim is responsible for porting Ghostscript, a PostScript language interpreter, to the ST platform, and for writing a GEM shell for it. In addition to Ghostscript, possible demonstrations include: MiNT, CS-TeX, and Unix Windows (only if we can rig access to a phone line). Y'all come!

As usual, we will also have available our ST and 8-bit libraries.

3446. Turbo assembler (turboass.prg) question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-11 01:16:28 UTC
From: max@neumann.cba.csuohio.edu
Message-ID: <1992Sep11.011628.11774@news.csuohio.edu>
Source record: 42801

The atari.archive.umich.edu program called "turboass.prg" is a nice assembler for the ST -- but written in German. After figuring out how much of it worked by trial and error and making educated guesses about German words, I still need to know one important thing:

How can I create linkable *.o files that work with C-language *.o files?

I managed to create the *.o file, but it had an incorrect format. My little initialization code called "main", and I was able to declare "main" as a global long. But the code which did:

jsr main

was compiled into:

jsr 0x4L

and it basically dropped "main" altogether so that the linker perceived the subroutine as being located at the absolute memory location 0x4L !! The turbo-assembler took my declaration of "main" as an acceptable external reference; the code assembled without error; but then didn't bother to signify that just at that point in the code (where it called main), the address needed to be fixed up to point to wherever the linker ended up placing "main."

3447. Even MORE TT030 help

Newsgroup: comp.sys.atari.st.tech

From: dud@hardy.u.washington.edu
Message-ID: <1992Sep11.053336.20699@u.washington.edu>
Source record: 42802

Ok, I took apart my TT for the first time. I now have a few more questions... How do I know what RAM is what? Right now I can only access the 4 megs of ST RAM. There are 4 megs of RAM on the motherboard, and also 4 megs on a daughter board directly under the HD. There is an empty socket that I've been told is for fast ram in front of the power supply. Since there are 8 megs in the machine, and only 4 seem to be accessable, I'd assume something is wrong. Should I unplug the board under the HD & plug it in in front of the HD? I don't think it'll fit in that small space. Are there DIP switch settings that make the TT RAM accessable? Thanks for any help or suggestions in advance....

It's actually 2MB on the motherboard and 2MB on the daughter. And the socket at the left front it indeed for the TT-RAM board.

>Since there are 8 megs in the machine, and only 4 seem to be accessable,

Nothing is wrong, and no twiddling of the DIP switches will add extra RAM to your machine :-). From what I've heard, only DIP switch 7 is used, and that sets whether or not the option for High Density floppies is available from the format dialog box.

Quite often, when the drives get old, the drive belt wears out
and either falls off or slips. Did you notice this about the
belt around the "spindle"?

This depends supposedly on the link format which your linker wants.
Basically, there are (at least) two formats: one proposed by
the company which wrote GEM (I just forgot the name), the other
proposed by GST. As far as I know the Turboass can produce both
formats. The first format is provided by the "SMALLDRI" button,
the other format ??? (I didn't use it yet).

Hope that helps, Cornelius.

> can a create a pipe between them somehow?

The server is the one that has to create the pipe. In the server you
should have code like:

```
fd = Fcreate("U:\\PIPE\\SOMENAME",flags);
```

The clients would then open "U:\PIPE\SOMENAME" and write requests to it;
when the server does an Fread() call on the file descriptor it received
above, it will receive those requests. There are various flags that can
be set in the "flags" field; see the MiNT documentation for details, but
likely flags=0 would be sufficient for most applications.

The MiNT utility programs lpr and lpd provide an example of how to
do interprocess communication; source code for these is available on
atari.archive in the file mntutl95.zoo.

3455. high speed modems and Spectre

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-11 16:31:57 UTC
From: ken@isgtec.com
Message-ID: <3267@isgtec.isgtec.com>
Source record: 42810

I've been noticing Spectre GCR handling the serial port very nicely
at 2400 baud with xon/xoff, but completely wiping out at 9600 baud +.
Since the ST/STe itself has problems at high speed, which is corrected
by using RTS/CTS and patch programs like TURBOCTS and SERIALFX, the
question is can I get Spectre to recognize these patches? I tried setting
this up in ST mode first and this seemed to make no difference.

The general corollary of this is can Spectre recognize and use any of
the various patch programs that are set up in ST mode? Does Spectre
map Mac toolbox stuff into calls to ST BIOS, XBIOS calls or does it
just write straight to the hardware?

Interesting! By coincidence the Sept '92 issue of The C Users Journal has an article "Using the PC's Parallel Port for Bidirectional Communications".

The parallel port is controlled by the Yamaha 'sound processor' (well, only the data pins). And this YSP permits use in both directions. I believe that on normal STs, the port isn't buffered so that you can use it as input !

But you haven't much BIOS support: you have to write in YSP's registers (there may be an XBIOS call for that) directly ! (doc on YSP registers shouldn't hard to find in atari books)

Anyway, you also can get data input through the only input pin of the atari-parallel-port: busy (I think almost all EPROMMERS that a conected through centronics use this 'trick')

3464. Mint + minix fs: any good backup programs/ideas?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-13 09:34:33 UTC
From: muts@fysap.fys.ruu.nl
Message-ID: <MUTS.92Sep13113432@ruunfs.fys.ruu.nl>
Source record: 42818
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I use mint + minix on my harddisk. I wonder what good method there is to make backups of my disk. The regular TOS programs won't work because they cannot handle longer filenames and links etc.

I would use simply gnutar to /dev/ps0, and with incremental tar's this would be feasible were it not that I produce multivolume tar's in that case. I do not like this idea because to restore something on say the 5th diskette I must read all previous ones than, with the risk that if somewhere on one of the backups is wrong the rest of the backup is unusable.

Does anyone have better ideas/programs to do this job? Thanks,
--

Sorry to be ignorant of such matters, but I presume this is a
one-way pipe, or do I just set read/write flags to make it two way (I
may not want a Client-Server model - just to be difficult!)

If not is there any way other than using one for reading and another
for writing for creating a two-way pipe. Who said 'ignorance was bliss'
I'll shoot them :-)

Thanks, (I wont bother anyone ever again after this - I promise!)

It's a two-way pipe by default. If you set the "read only" bit in flags,
it will be a one way pipe.

3468. Official Keycode Guidelines of Atari

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-14 14:20:48 UTC
From: avgroeni@cs.ruu.nl
Message-ID: <1992Sep14.142048.18305@cs.ruu.nl>
Source record: 42823

I suppose you've all heard it: Atari has official key code guidelines.
Of course, we couldn't expect them to come up with REASONABLE propositions:

code operation objection

^O Open OK
^N New file All right
^Q Quit Of course
^F Find Sure
^G Find Next Fine
^H Replace ??? Never heard of this. I thought it was

^R Replace
^T Replace Next

OK. What I did in my text editor is this: you use search all which
marks all the targets that are found. (Multiple selections are NOT
easy to implement...) Then you use ^H which replaces a multiple
text buffer (filled in by the search routine with either one replacement,
or in case of regexp s&r, a different replacement for each item found)
with the selected fragments that were found.

^W Close Window Well God D******* why this? I thought ^W was cycle windows
and (maybe only in Germany, but after all that is the leading ST territory)
^U was close window. OK, I implemented ^U for close window as well as
^W, and put cycle windows on Alt-Q. (With all possible dangers of someone
accidentally using Control-Q :)

This is all as far as I remember. They could have specified more, though,
to my taste. Does anybody have any suggestions/comments to what I've written?
Shouln't we **.tech readers make a more extensive list with more elaborate
comments like I've done here, and then distribute it widely (somewhat like the
picture format document that went round the world some years ago)?

To use the parallel port for both input and output, you need a special cable.
This cable has the data and status/control lines crossed. This way you send
data using the data lines and receive data on the status lines. For a
really cool article on this subject, see this month's "C Users Journal",
September, 1992.

The speed improvement of 2 or more, are you comparing
assembler versus the C code equivalent?

How do the VDI calls compare? (specfically the
raster operations ?) Are they usefull only for
prototyping or can one implement a reasonable animation?

I am currently using the VDI calls to cut and paste
Neochrome type images, and they seem reasonably fast
but then again, I'm not making many repeated calls.

If these calls are poor performers, is there assembly source
code avaiable to replace them?

3471. Re: digitized sound, how to?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-14 17:46:51 UTC
From: eker@loria.crin.fr
Message-ID: <476@muller.loria.fr>
Source record: 42774

In article <Bu8u83.KCG@iat.holonet.net>, wilsont@holonet.net (Timothy Wilson) writes:
|> Hi again. ok you tech guys...
|> how do i get sound samples out of my ST?

Well this is my understanding of how you play samples using the PSG; its
only theoretical cos I've never tried it myself...

The basic idea is that when you change the volume on the PSG the chips it is lazy
and generates

```
_ _ _ _
| | | | | | | | _ _
| | | | _ _ instead of | | | |_| |_| |_
_| |_| |_| |_| |_ _| |_|
```

ie it only varies the top of the waveform & leaves recentering to the
decoupling capacitors in the audio amp section.

Now the frequency is set high enough & the volume is changed fast enough
two things happen:
(1) The very high frequency components get lost in the works.
(2) The changes in volume cannot be recentered by the decoupling caps and
themselves constitute an AC waveform (which of course itself gets centered).

This is kind of like the way AM signals get demodulated in a radio set
where the lazyness of the PSG chip plays the role of the diode and the
inherent capacitance of the audio section shunts off the high frequency carrier.

So the basic idea is to set the playback frequency on the 3 square wave channels
as high as possible (to be the carrier) and vary the volume to encode
your PCM samples as amplitude modulation.

Now the volume on the PSG is logorithmic rather than linear ie it goes up by a ratio of
sqrt{2} for each step. So by combining all three channels you can get
a pretty fair approximation of 8bit resolution (rather than the 5.5bit resolution
you would expect if the volume was linear).

So what you want is an interrupt routine that runs at your chosen playback
frequency and for each sample in succession looks up the volume for each of the
3 channels in a precomputed table (indexed by the sample) & sets them.

|> is optimized C fast enough to handle this job?

Not a chance.

|> I've looked in my TOS book, but only the PSG s there, and it doesn't seem to
|> have a way to control the speaker directly.

Well there is but you need to use amplitude modulation.

|> I also looked at noisetra.s, (68k code for noisetracker), but it seems not
|> a single standard call is used (therefore i couldn't reference it)

It accesses the PSG chip directly; TOS calls are _far_ to slow.

|> books, code, ftp site would be helpful!

I've not seen the technique descibed in any book but if you have
noisetra.s then you already have the code.

Steven

3472. AES bug ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-14 18:14:57 UTC
From: wallmann@backus.pu.informatik.th-darmstadt.de
Message-ID: <1992Sep14.181457.16038@news.th-darmstadt.de>
Source record: 42825

I am (for whatever reasons) having enormous problems with the graf_...
calls in the AES library (TOS 1.4). The following little program, for instance
shows a weird behaviour of the graf_mkstate call. If you press the mouse
button for the first time, it stops and waits for a release, the other times
it just (correctly) samples the mouse state.

```
/* Compiled and Linked with Pure-C */
#include <aes.h>
#include <stddef.h>
#include <stdio.h>

main()
{
int i, x, y, state, shift;

for( i = 1000; i--;)
{
graf_mkstate( &x, &y, &state, &shift); /* press left mouse button */
printf( "%d %d %d %d\n", x, y, state, shift);
}
}
```

I also have had problems with graf_watchbox and graf_dragbox, which for no
apparent reasons get stuck sometimes (but not predictably).

Does anyone have a clue or the same woes ?

Nat!
P.S.F.:
I am writing my first real GEM program and at least in the version I have
GEM seems to be reeking of bugs. Apart from the most basic windowing and
object redraw mechanisms, it appears that one has to rewrite/extend all
of Atari/DRs code to get decent results.

The ST's 8-bit printer port is the Yamaha PSG's I/O port B which is
bidirectional. You read it with (prt_in is a C char)

```
prt_in = Bconin(0);
```

That's what the Profibuch says. But NOTE: The port is normally programmed as
output. If you connect a "talking" device to it and it (the port) is
"talking", too, you'll probably destroy the PSG chip. You have to make
sure that only one device is talking, i.e., outputting at a time.
That's why I haven't tried out the above in practice - I would hate
replacing the PSG.

A safer way perhaps would be to bypass the BIOS function and divide the
PSG port into two: x inputs and 8-x outputs. For that, you would have
to know how to program the PSG - I don't...

BTW: the 8-bit printer ports of PC's are not ALWAYS bidirectional - some
are, some aren't. The Centronics port, however, has more than 8 lines -
8 are data, the rest are control. The control lines can be used as input
even in the cases where the 8-bit data port itself is not bidirectional.
The same applies to the ST which, unfortunately, has less control lines.

I have to agree this one makes no sense. The only use I've seen
in various text editors I've used for ^h is unmark block. Speaking
of which, did they suggest keycodes for block start and block end.
It seems half the editors out there make you use the mouse to mark
blocks, with no support for keyboard alternatives. ;-(

>
> ^W Close Window Well God D******* why this? I thought ^W was

German editors are the only ones I've seen with cycle windows. I
like the alt-1, alt-2 etc to pick windows better, myself.

> ^U was close window. OK, I implemented ^U for close window as well as
> ^W, and put cycle windows on Alt-Q. (With all possible dangers of someone

I'd rethink alt-q for cycle windows. There's a lot of editors that
use alt-q for quit.
While it's nice to see a standard defined, with so many gem based text
editors out there already with totally incompatable keymaps, I think the
best thing to do is follow the new standard, but allow for remapping, like
Tempus and a few other editors do.

> |---|--building the foundations-|---|---|---| george@electro.com

I'm not exactly a 'demo-wizard', so I may be wrong (well
I hope not completely)

VDI raster operations should be 'device-independent'
and of generic functionality (it is possible to copy
from one screen format to another, for example)
This means it can't be fully optimized for 1 particular
application. So it sure is slower than direct screen access
The less processing is needed, the bigger the speed difference:
with sprites, the difference is BIG !

If you wish to do animations with VDI, you'll need
NVDI (cause VDI is not assembler-optimized but compiled
C) and maybe a processor a bit more powerful than 68000 8Mhz !

For source assembly code, I don't know: check at a.a
(default answer :-))

Can anyone a bit (at least) more involved in demos help ?

3479. Hardware support for m/t on Falcon?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-15 11:20:35 UTC
From: pbh@jake.cc.wayne.edu
Message-ID: <1992Sep15.112035.633@cs.wayne.edu>
Source record: 42832

I've been watching the posts about the Falcon's specs and MultiTos, the multitasking OS and I don't recall seeing any info about this. So I ask, does the '030 have hardware memory protection built in, or is there a chip on the Falcon mb for it, or is there no protection for processes? I've heard talk about ports of BSD to the falcon and was wondering useful this might be if that protection isn't built in to the machine.

It isn't possible to split the 8-bit-wide port into an input and an output
section. You can only change the data direction for the entire port.

The Falcon makes use of the 68030's built-in "memory protection". This is the
primary reason that you are not likely to see an official Atari MultiTOS upgrade
for the 68000 series machines.

3482. PLEEASE HELP: GDB won't load my program

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-15 18:48:07 UTC
From: svleest@jobim.crhc.uiuc.edu
Message-ID: <195b57INN454@roundup.crhc.uiuc.edu>
Source record: 42834

I am having problems getting gdb, the GNU debugger, to work.
When I compile a program for debugging and then use sym-ld to
build the symbol table, all is fine. I then run gdb. I can use
"info function" to list all the functions in my test file.
HOWEVER, if I then try to run the program, it exits IMMEDIATELY, with
the message:

Program exitted with status = -32

This happens regardless of how simple or complex test.prg is.
What am I doing wrong? I have noticed that if I use examine
to look at the program data, it reports everything is 0 (I use x/10d at
multiple locations, and everywhere it is 0). Is this because
gdb does not actually load the program until you command it to
"run", or is this part of my problem? I have the following versions:

gdb 2.6 Patchlevel 18
gcc 1.40 Patchlevel 2
gcc-ld and sym-ld Patchlevel 27
gulam cli

I used the following command sequence:

```
>gcc -c -g -D__NO_IN_LINE__ test.c
>gcc -o test.ttp test.o
>sym_ld -r -o test.sym crt0.o test.o -l gnu
>gdb -e test.prg -s test.sym
*run
```

(where ">" is the gulam prompt, and "*" is the gdb prompt) and I
get the error described above. I have tried this with nothing else
but my hard disk driver, gulam, and gdb loaded (no ACCs, etc.) and
it still bombs.

Any help would be greatly appreciated!

3483. GFA: Interrupt programming fails in TT-RAM

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-15 20:34:46 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1992Sep15.203446.141116@rrz.uni-koeln.de>
Source record: 42836
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi everyone,

I recently got a hold of the File-Info/Config CPX and used it to set the TT-Ram bits of a program I wrote and compiled under GFA basic 3.6. The program contains a procedure that is called every 1/5 seconds by the command "EVERY 40 GOSUB procedure". While this has worked fine with the TT-Ram (Prg) bit unset, it doesn't work when this bit is set.
To investigate this phenomenon, I wrote a test program (included below). It basically consists of the EVERY command, followed by a loop that should then be interrupted by interrupt procedure at regular intervals. With this test program, I found out the following:

1. If there are 4 PRINT commands between the EVERY command and the loop (let's call this program "TEST_A.PRG"), the interrupt works in ST Ram and doesn't work in TT Ram.
2. If there is just one PRINT command between the EVERY command and the loop ("TEST_B.PRG"), the interrupt (now read this!) works in TT Ram and fails in ST Ram!
3. Lately, I installed the ARROWFIX.PRG in my auto folder. Since then, TEST_A.PRG runs properly with or without the TT-Ram bits set, and TEST_B.PRG fails with both TT-Ram bit settings.

Fortunately, my original program seems to belong to the "A"-category, so it is magically fixed by ARROWFIX. However, I am severely confused. Any idea how these *weird* findings can be explained?
In the GFA basic manual it is explained that the EVERY command is realized with the etv_timer vector ($400), if that is of any significance.

Greetinx, Jan

+- Jan Kim -- X.400: S=kim;OU=vax;O=mpiz-koeln;P=mpg;A=dbp;C=de -+
| Internet: kim@vax.mpiz-koeln.mpg.dbp.de |
| |
----=< hierarchical systems are for files, not for humans >=-----

P.S.: You may flame me for programming in GFA basic if you must. But please include code for implementing equivalents of the EVERY command in your favorite language in this case. ;-)

Here's the code of the test program:

```
' TEST_B.GFA
$I+
$U+
~TT?
CLS
ON BREAK CONT
DIM mbuf&(7)
EVERY 40 GOSUB show_interrupt
PRINT "Every is now activated"
'
' Un-comment either the three prints or the wave to obtain TEST_A.GFA
' PRINT
' PRINT
' PRINT
' WAVE 1,1,0,1000,20
'
t%=TIMER
REPEAT
$U
IF TIMER-t%>200
PRINT "Hi there, the main loop has idled for another second..."
t%=TIMER
ENDIF
UNTIL MOUSEK=2 OR INKEY$=CHR$(27)
$U-
$I-
PRINT "see ya"
~INP(2)
EDIT
'
PROCEDURE show_interrupt
EVERY STOP
PRINT "Hi, I'm the interrupt procedure."
EVERY CONT
RETURN
```

3484. Bootstraping a gnu development system.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-16 00:34:51 UTC
From: ak751@cleveland.Freenet.Edu
Message-ID: <195vfbINN588@usenet.INS.CWRU.Edu>
Source record: 42838

The specs on the new atari falcon have got me thinking about selling either my mac, or my 486, or both. If I could bootstrap a gnu developments system I would be convinced to switch. Can this be done? Are there binaries available? How about the c libraries and include files? Also, what is this MiNT? Is it some kind of alternative unix-like operating system. Does minix for the ST run in protected mode? Does it use the virtual memory features of the 68030?
Thanks in advance for any info which may serve to dispell my ignorance of atari computers.

Over the past 6 months, I have been developing "AMS", the Atari Machine Specific library. It is for G++ program development, primarily focussed on games (since non-real-time applications should generally avoid machine specific coding).

For a simple example of what it makes possible, take a look at the COMBAT game, now in the /atari/games directory (and /atari/newitems), under the name "combat.zoo". No source is provided as yet, but it will all be free. If you have G++ set up, and would like to use AMS, mail me, and I'll make it available. Combat is the first full game I've made with AMS, although I did port GNUChess to a graphical interface with an older version of AMS (just to try out the library - I'm not into chess these days), which is also in the games directory.

I don't really intend to support "COMBAT", but I'll add the "Tank Pong" feature... Great Scott - how could I forget!

> file).

Yes, for NEWDESK.INF, there is: take GEMRAM V1.1 and SHBUF. Gemram copies the GEM into the RAM, so that SHBUF can patch the size of the Shell-Buffer. This operation cost you much more then only the space for a bigger NEWDESK.INF, but there is no other way around.

Source record: 42855

graf_mkstate() does have its problems in early TOS versions.
In 1.4 you can live with it, but in 1.0 and 1.2 you will always have a little
delay before the function returns. This has nothing to do with releasing the
mouse buttons, although it may look as such at first.

hope this helps.

I know this subject has been discussed over and over before, but that was before I had access to the net, so: apologies to all.

I want to upgrade the memory of my atari 1040stfm, and I know it can be done without spending heaps of money on simple carrier boards I can make myself. So, does anybody of you know how to upgrade?

This is what _I_ know:

a 1040 has two memory banks of 512K

You could replace the chips of either of the banks with larger ones and get 0.5 + 2 = 2.5 megabytes.

That would involve making a carrier board to do it neat.

Soldering and etching isn't a problem for me, so I only need some advice and the schema. If one of you has it, could you please email it to

erikp@stack.urc.tue.nl

Source record: 42851

Here's a compilation of what I heard so far. I'm beginning to see some
philosophies to design a bigger range of more or less agreed key codes.
Keep contributing!

Close Window

The Control-W for close-windows is used on the macintosh (Command-W) - maybe
that's why CTRL-W was choosen for the Atari guidelines. And, since you state
that CTRL-W is used for 'cycle windows' at the moment: how many programs *do*
have a 'cycle-windows' option?
--
Hendrik Jan Veenstra hjv@phil.ruu.nl

AVG: Good argument. Also already supported by lots of software. Would also
support ^U, though.

Search and Replace

Although remarkable, I think Atari's control H is a source of new creativity
(as it was for me with my text editress Edith). Let's stick to that, though
let's also keep ^R and ^T reserved for Replace/Next.

Cycling Windows

John Henders (jhenders@jonh.wimsey.bc.ca)

German editors are the only ones I've seen with cycle windows. I
like the alt-1, alt-2 etc to pick windows better, myself.

AVG: A good idea, but lacks a definition of what exactly the alt-1 and alt-2
and so on mean. Not window handles, I hope, for those are most likely
to exceed 10 in the near future.

John Henders:

I'd rethink alt-q for cycle windows. There's a lot of editors that
use alt-q for quit.

Save and Save As...

Chris Herborth:
^s should be Save
Shift-^s should be Save As

AVG: One should definitely make more use of shift-control in the future, for there are indeed lots of functions with two similar alternatives, like save and save as... So this seems to me an excellent idea, although I'd like to reserve ^m for save as AS WELL.

Other ideas like this:

^p Print
Shift-^p Printer Queue

^w Close Window
Shift-^w Close All Windows

Selection/Blocks/Buffers

There should be something for Clear Selection at least; I (AVG) suggest

^a select all (fixed already)
^i invert selection (if you can, that is; Edith can!)
^e clear selection (`erase marks') I've also seen ^h for this but that's clearly out of the question.

General:

John Henders:

While it's nice to see a standard defined, with so many gem based text editors out there already with totally incompatable keymaps, I think the best thing to do is follow the new standard, but allow for remapping, like Tempus and a few other editors do.

AVG: I totally agree on this point. I would like to add here that it is worth looking at a lot of other programs, and then try to combine as many codes as possible: for Edith (it seems that we're only talking about text editors here:- this is not true) I combined Tempus, TC, GFA Assembler codes; lots of actions also have a function key, like

(I might be slightly wrong with these because I don't use them myself, with the exception of F10)

F6 Special Characters (GFA Assembler)
F7 Search Next (Tempus)
F8 Delete Line (Lots; note: Germans use ^Y which usually turns out to be ^Z for us provided they didn't use the complete scan code, in that case the whole combination is impossible!)
F10 Clear Selection (Tempus: clear block marks)

The comments with F8, ^Y, ^Z bring us to a very important point: we should point out a way of reading key codes, so that in the future, German and particularly French users will not have to suffer from their incompatibility. Unfortunately, codes with alternate are impossible to read independently of their place on the keyboard (the scan code does not contain an ascii value), but the Control combinations

are, provided that you AND out the ascii code and check k_shift for the 'control' part.

Jan, anyone who flames another for writing programs in a language that is not their favorite for whatever reason is only proving to the world what a "flaming idiot" they really are. These people have the same low mentality as the "my computer is better than your computer" crowd. Just ignore them as they are not worth the bandwidth. If it works for you then that's all the justification that is needed, IMHO.

Unfortunately, I don't see anything wrong with your program listing so it must be a TT-specific problem. Sorry.

Another suggestion for Atari, and otherwise for someone else
who knows about speech synthesis on the ST: preferably when
the Falcon comes out on the market, there should be a neat way
to have your applications give spoken form alerts etc. (Like on
the NeXT a sweet woman's voice tells you `Your Printer is Out
of Paper'

There are at least two ways this could be done:

1. Implement an Xbios function

say(char* sentence, int accent);

This especially fits into the idea of a 'dedicated
multi-media machine' Atari like to claim they are
working on.

2. Design a program that stays resident (executed by
profile) and can receive messages from applications
and then handles speech requests from applications
in FIFO order.

[sorry if you've seen this before but my first attempt to post it appears to have failed - at least it's not visible at my site]

In article <Bu8u83.KCG@iat.holonet.net>, wilsont@holonet.net (Timothy Wilson) wr
ites:
|> Hi again. ok you tech guys...
|> how do i get sound samples out of my ST?

Well this is my understanding of how you play samples using the PSG; its
only theoretical cos I've never tried it myself...

The basic idea is that when you change the volume on the PSG the chips it is laz
y
and generates

```
_ _ _ _
| | | | | | | _ _
| | | | _ _ instead of | | | |_| |_| |_
_| |_| |_| |_| |_ _| |_|
```

ie it only varies the top of the waveform & leaves recentering to the
decoupling capacitors in the audio amp section.

Now the frequency is set high enough & the volume is changed fast enough
two things happen:
(1) The very high frequency components get lost in the works.
(2) The changes in volume cannot be recentered by the decoupling caps and
themselves constitute an AC waveform (which of course itself gets centered).

This is kind of like the way AM signals get demodulated in a radio set
where the lazyness of the PSG chip plays the role of the diode and the
inherent capacitance of the audio section shunts off the high frequency carrier.

So the basic idea is to set the playback frequency on the 3 square wave channels
as high as possible (to be the carrier) and vary the volume to encode
your PCM samples as amplitude modulation.

Now the volume on the PSG is logorithmic rather than linear ie it goes up by a r
atio of sqrt{2} for each step. So by combining all three channels you can get
a pretty fair approximation of 8bit resolution (rather than the 5.5bit resolutio
n
you would expect if the volume was linear).

So what you want is an interrupt routine that runs at your chosen playback
frequency and for each sample in succession looks up the volume for each of the
3 channels in a precomputed table (indexed by the sample) & sets them.

|> is optimized C fast enough to handle this job?

Not a chance.

|> I've looked in my TOS book, but only the PSG s there, and it doesn't seem to
|> have a way to control the speaker directly.

Well there is but you need to use amplitude modulation.

|> I also looked at noisetra.s, (68k code for noisetracker), but it seems not
|> a single standard call is used (therefore i couldn't reference it)

It accesses the PSG chip directly; TOS calls are _far_ to slow.

|> books, code, ftp site would be helpful!

I've not seen the technique descibed in any book but if you have
noisetra.s then you already have the code.

3504. 68K Trap Stack formats

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-16 20:39:14 UTC
From: rossin@hpfcso.FC.HP.COM
Message-ID: <16620008@hpfcso.FC.HP.COM>
Source record: 42860

Ok, I'll admit that I'm blown away. In the world of Atari 68K machines, user level code makes calls to the OS with the use of TRAP instructions. This all seems fine until you consider that Atari uses 68000 and 68030 processors. After a TRAP instruction the stack frames look different on the two processors:

68000 68030

SSP---->Status Register SSP---->Status Register
PC PC
User parameter2 Stack Format
User Parameter1 User Parameter2
User Parameter0 User Parameter1
User Parameter0
The 68010 and up all put that nice little word known as the stack format on the stack. This is for that virtual memory support thing so that one can determine how to restart an instruction that caused a page fault.

This means that TOS and GEM need to know which processor they are playing on to access the user level parameters. Also, when someone writes code that intercepts a trap vector, that code needs to know which processor it is running on in order to get the correct displacement to the parameters.

My questions are:

1. Did Atari redo nearly every line of code for the new ROMs in the 030 machines (TT030/falcon)?
2. Are people who write code that steals the trap vectors who say that their code runs on all Atari machines really smart?
3. Is that famous guy who is putting together an 040 based upgrade for 68000 machines writting his own TOS and GEM or does he require one to buy TT030 ROMs?
4. Am I an idiot who can not read data books from Motorala correctly which would make the previous questions stupid?

Please help me out.

Ted Rossin the Butt Hole not Inc.

I want to add another question concerning the Traps used in TOS:

as I understand it, the trap instruction does not do anything with
parameters on the stack; but as TOS runs un system-mode the stack
remains the same and the parameters are still visible. Otherwise they
would have needed to be in registers.

Is this true? If so, why does TOS use the expensive trap instruction
when it is not needed to switch from user to supervisor mode?

evnt_multi() dosen't always fill out the return parameters correctly. It is
easily reproduceable, and a known bug (also TOS 1.04)...
You have to call graf_mkstate() after evnt_multi() to get the correct values.
graf_mkstate() is much faster than evnt_multi() when doing mouse-tracking.

> 1. Implement an Xbios function
>
> say(char* sentence, int accent);

Make that >> say(char *string, int accent, int language); <<

Ofcause the function could just read the language in the OS-header, and if the program was written in german, then the function could translate the german string into say - danish, and say the message - real easy.

The best way may be to have a general translation build into the function as in
Function >>say()<< XBIOS 666:

say(char * sentence, int accent, int source_language, int dest_language)

where source_language and dest_language, is ordered as in the OS header.
the accent is a packed short with the following meaning:

| female | freq of pitch change | pitch | freq of volume change |... |

That is easy, now all Atari have to do is to implement it...

Sure. There are binaries available for gcc, GNU make, bison, flex, perl, bash, and pretty much all of the other common GNU tools. All are available from atari.archive.umich.edu, and run under the native operating system (TOS) or under MiNT (see below).

> Also, what is this MiNT? Is it some kind of alternative
> unix-like operating system.

MiNT is a TOS-compatible operating system that adds a lot of Unix like features (pipes, signals, multitasking, job control, etc.). It's freeware, there's a complete C library (mostly ANSI and Posix compatible) available in source and binary form, and lots of utilities (including tcsh, ksh, and bash) have been compiled to take advantage of its features. (Plus, it will run well-behaved TOS programs, like the GNU utilities mentioned above.) Source code to MiNT is also available. Atari has announced that their forthcoming multitasking version of TOS will be based upon MiNT.

> Does minix for the ST run in protected
> mode? Does it use the virtual memory features of the 68030?

It does run in protected (supervisor) mode; all OS's on the Atari do, as far as I know. However, the 68000 doesn't offer much in the way of memory protection, even in supervisor mode. The 68030 could, but so far as I know minix doesn't (yet) run on the 68030. This may have changed recently.

MiNT doesn't take advantage of the 68030's MMU. Statements from Atari indicate that MultiTOS (when it's available) will offer memory protection.

An excellent idea (and in fact it could be done for the ST, too).

> There are at least two ways this could be done:

> 2. Design a program that stays resident

You left out:
3. Implement a MiNT/MultiTOS device driver for speech.

I think this is the best option; then the user could (from a CLI) do something like:

copy file.txt u:\dev\speech

to have a file read aloud.

> the two processors:

Yes, but you'll notice that they're not much different; on a 68000,
you add 6 to the current SSP to get to user parameters, on a 680x0 x >= 1,
you add 8.

Atari's TOS startup code for TOS 1.6 and later determines what kind of
CPU the program is running, and sets a variable in low memory (and
also a cookie in the cookie jar) accordingly. I forget the exact address
of the variable, but for the sake of argument let's assume that it's
$59e. Then the TRAP code would look something like:

tst.w $59e ; or whatever the right address is
bne not000
is000:
lea 6(sp),a0
bra continue
not000:
lea 8(sp),a0
continue:
; now A0 points at the user's parameters

(Note that I've also omitted the code for getting the parameters if
the call was made from user mode; that would just be a move.l usp,a0
after the appropriate test.)

So the same code can easily be made to work on 68000 and 68030 machines,
provided that you're careful to check the appropriate variable.

There are TWO stack pointers on the 68000 (and 3 on the 68030, but the third one is not used in the Atari's OS). The user stack pointer, usp, is register a7 in user mode. The supervisor stack pointer, ssp, is register a7 in supervisor mode, and the usp is accessible through a special move usp,aN instruction. That's how the OS is able to get the parameters from the user stack.

> Is this true? If so, why does TOS use the expensive trap instruction
> when it is not needed to switch from user to supervisor mode?

Au contraire, the trap instructions (or a similar exception, e.g. the line A and line F emulator traps, or the various bus error and similar exceptions) are the only way to switch from user to supervisor mode. User mode code is not permitted to change the status register or to otherwise enter supervisor mode without going through a special trap; otherwise, there would be no way to provide security.

3519. Inline assembly in gcc

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-17 17:51:38 UTC
From: dawinic@eos.ncsu.edu
Message-ID: <1992Sep17.175138.19717@ncsu.edu>
Source record: 42872

Can someone please explain to me how to implement inline assembly code
that will access non-local variables in gcc.

e.g.: I have been using the following inline routine using LaserC to
detect if GDOS was present:

```
void foo()
{
int GDOS = 0;

/* Find out if gdos is installed */
asm {
move.w #-2, D0
trap #2
cmp.w #-2, D0
beq gdos_not_installed
move.w #1, GDOS(A6)
gdos_not_installed:
}

if (GDOS) {
/* GDOS installed... */
}
else {
/* GDOS not installed... */
}
}
```

I have translated all of this "routine" into the gas syntax, except:

```
move.w #1,GDOS(A6) ==> movew #1,a6@(GDOS) ???
^^^^
||||
```

How do I declare this variable properly in order to keep this inline.
(I know one solution is to make this a separate subroutine in order to
use the stack for passing and returning values).

For me, ^H is 'Revert'. This is what my preferred text editor (qed), my preferred RSC editor (Interface) and PureC use (and it's the same shortcut as on the Mac).

> ~~~~~~

In GFA Basic (I'm using 3.6) the resolutions are found by:

```
x_res%=WORK_OUT(0)
y_res%=WORK_OUT(1)
```

Also helpful is

```
number_colors%=WORK_OUT(13)
```

I just had to find these for a program myself! :)

Perhaps, but using graf_mkstate() and evnt_multi() in the same program
may cause terrible problems, since evnt_multi() assumes that nobody
collects samples of the mouse state behind its back, and will get out
of sync if you do.

I've never heard of the bug you mention, perhaps you can give
some details?

There are at least three: Pure C, Lattice C, and GNU C.

I own Pure C and can recommend it, even if your German isn't too good (mine
isn't), it is about $250/#125 (using out of date but convenient
exchange rates :);
Lattice C is also a commercial program; GNU C is public domain,
but I understand it requires *at least* 2M of memory, and is somewhat
slow.

I hate to contradict you, but the ST's parallel port is already
bidirectional, I know I made robot arm send data back through it. I
used standard bindings for reading from ports in Basic (the pascal
like one whose name I can't come up with currently). The ST does not
have all the control and status lines that PCs do, so it cannot notify
you if it has new data, or use PC parallel port communication schemes,
but you simply poll the port when there is incoming data. I needed no
special cabling, but did use all the strobes to get data into the ST.

First: why does your text-layout get so terribly f*cked up so often? It's
horrible to read.
Second: about the independant keycodes: with the Interface RSC comes a module
that implements so-called normalized keycodes (NKCC) - it's supposed to provide
country independant keyboard support. Linkable with C programs, etc., etc.

3527. Need to get filenames from unix machine to st intact

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-18 00:48:05 UTC
From: selick@csa.bu.edu
Message-ID: <96249@bu.edu>
Source record: 42876

I need to be able to get all of the files in a given unix directory to my st with all of the filenames intact. This includes spaces, & signs, and # signs. The reason is that my Yamaha TX-16w sampler which reads ms-dos disks, can also read those characters. The files are archived in tar format, but I could convert them if necessary. Any suggestions?
-Steve <selick@csa.bu.edu>

3528. Re: Inline assembly in gcc

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-18 02:14:42 UTC
From: warwick@cs.uq.oz.au
Message-ID: <10325@uqcspe.cs.uq.oz.au>
Source record: 42879

dawinic@eos.ncsu.edu (DAVID AARON WINICK) writes:

>Can someone please explain to me how to implement inline assembly code
>that will access non-local variables in gcc.

GCC has very powerful argument validation/passing features for asm.

```
>void foo()
>{
> int GDOS = 0;

> /* Find out if gdos is installed */
> asm {
> move.w #-2, D0
> trap #2
> cmp.w #-2, D0
> beq gdos_not_installed
> move.w #1, GDOS(A6)
> gdos_not_installed:
> }
> ...
```

Firstly, this can be done by standard bindings at the end of vdibind.h,
but for the sake of exercise (and at the risk of making a typo), this
translates to:

```
void foo()
{
int GDOS = 0;

/* Find out if gdos is installed */
asm ("
movew #-2,d0
trap #2
cmpw #-2,d0
beq gdos_not_installed
movew #1,%0@
gdos_not_installed:
" : /* Outputs: */
/* none */
: /* Inputs: */
"a" (&GDOS)
: /* Destroyed registers: */
"d0"
);
...
```

(You could also do it by using GDOS as an output value, but I'm still a bit confused about INPUT OUTPUT variables (which it might be, since it starts off with value 0).

I found this out by reading the GCC documentation - but it is a bit sketchy - it is easier to simply look at the examples of how things are done in the osbind.h file, and other places asm is used.

The details though, appear in the Machine Description sections of the GCC installation manual.

As you can see, with all this explicit declaration of destroyed registers, and stuff, the compiler can generate very efficient code.

Lattice C lets you mark blocks with key codes.
I find there F1 and F2 (resp. begin and end) very handy.

>>

No, again Lattice C (definetly not german:-) allows you to cycle windows too.
They use ^V for this (at least in 5.2.x, as I haven't use 5.5 not that much yet).

For closing windows, I like the C as used by the desktop. So why not make
it ^C within applications.

The above for picking windows alt-1, etc, seems a good idea to me!

>> ^U was close window. OK, I implemented ^U for close window as well as
>> ^W, and put cycle windows on Alt-Q. (With all possible dangers of someone
>> accidentally using Control-Q :)

Do _NOT_ use Alt keys, as they are used in some countries to allow other
characters to be entered, which are not in the standard letter set!!!

In <16620008@hpfcso.FC.HP.COM> rossin@hpfcso.FC.HP.COM (Ted Rossin) writes:

]Ok, I'll admit that I'm blown away. In the world of Atari 68K machines,
]user level code makes calls to the OS with the use of TRAP instructions.
]This all seems fine until you consider that Atari uses 68000 and 68030
]processors. After a TRAP instruction the stack frames look different on
]the two processors:

] 68000 68030

] SSP---->Status Register SSP---->Status Register
] PC PC
] User parameter2 Stack Format
] User Parameter1 User Parameter2
] User Parameter0 User Parameter1
] User Parameter0

Wrong, i think. The user parameters will generally be on the user stack,
and the status reg, pc and stack format on the SSP.

]The 68010 and up all put that nice little word known as the stack format
]on the stack. This is for that virtual memory support thing so that one can
]determine how to restart an instruction that caused a page fault.

]This means that TOS and GEM need to know which processor they are playing
]on to access the user level parameters. Also, when someone writes code
]that intercepts a trap vector, that code needs to know which processor
]it is running on in order to get the correct displacement to the parameters.

]My questions are:

] 1. Did Atari redo nearly every line of code for the new ROMs in
] the 030 machines (TT030/falcon)?

Let we hope so :-). Probably not -- they might have heard of modular
programming.

] 2. Are people who write code that steals the trap vectors who
] say that their code runs on all Atari machines really smart?

You can steal the trap vectors with looking only at the USP for the
normal traps. Exceptions (buserr, floating point emul) are a different
ball game.

] 3. Is that famous guy who is putting together an 040 based upgrade
] for 68000 machines writting his own TOS and GEM or does he
] require one to buy TT030 ROMs?

Isn't tos 2.x safe for 680[34]0 machines? I would go that way!

When did Atari publish official keycode guidelines? I don't believe I ever received anything from Atari that dealt with this issue.

As far as I know, Atari has not sent out any official documentation to US developers since January--at least I haven't received any. So far, I have not received any information from Atari even hinting that they plan on releasing a new computer (the Falcon) or a new operating system (MultiTOS).

Am I being left out, or is this the experience of other developers too?

Just to put in my $.02, I like the alt-1, etc. too. Like someone posted, what if you have more than 10 windows? First it means you are running to d*mn many programs at once. :) Second, there should be a nice way of accessing the other windows - how about alt-"+" (on the keypad) and alt"-" to cycle up/down through the windows?

Are there programs that absolutely must have those?

>
>Lattice C lets you mark blocks with key codes.
>I find there F1 and F2 (resp. begin and end) very handy.

Yes, but shift F4 to remember a block and shift F to delete are
a bit clumsy, unless you have awfully long fingers. ;-(Personally, I
like cntrl B to mark the beginning and cntrl E to mark the end, then
the standard "mac'isms" of cntrl C,V,E,H,etc for copy, paste, delete,
and unmark. This is how I reconfigured TempusII. Also, to close a window,
I used cntrl N for NEW. If no file is given, the window deletes. Then I
configured alt 1-4 for selecting between the windows. I find switching
between editors a pain in the b*tt, but at least if the editor allows
reconfiguring of the keyboard, it's a little less painful. Then all you
have to do is learn the configuration language.
Of course, some editor's design philosophys don't allow certain
conventions. For instance, I can't figure out a way to mark the end of a
block in emacs. Seems someone decided that start of block to current
cursor was all that was necessary.

>>>

Well, much as cntrl C is a standard abort in tos applications, it's
commonly used for copy block ap[plications in a number of editors.

But doesn't HiSoft still use alt-q for quit?

With all the different "standard" key commands out there, it's about as
much use for anyone to define a "standard" now as it is to define a
"standard" language for the whole world to speak. The only reasonable
solution is to all low remapping, and maybe define "standard" functions that
should be the bare minimum present in an editor.

Lattice C Version 5.5 sells for 99 pounds in europe. Here is an excert from the ad itself, I saw this in ST FORMAT magazine..

Lattice C V5.5 is a versatile and powerful development system for the popular C programming langauge, adhering extremely closely to the ANSI standard. It contains the most complete set of C libraries to be found on the Atari 68000 computers, Gem based installation program, multi-window editor, project manager and lots more. Requires 1 Meg.

Well that's the ad I hope you find what your looking for.

ST MASTER -- The Programming Wizard

3538. Summary of how to get x,y resolution

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-19 23:37:43 UTC
From: Conan.Ford@debug.cuc.ab.ca
Message-ID: <1992Sep19.233743.15812@debug.cuc.ab.ca>
Source record: 42742

Thanks to everyone who responded to my post asking how to determine the screen x and y boundaries.
Someone requested that I post a summary of the responses, so here it is (I have only been able to try the work_out(0), work_out(1) in GFA Basic so far, and it looks like they are valid after making a call in GFA Basic that uses a GEM function.)

ntomczak@vega.math.ualberta.ca suggested using vq_extnd() - opcode 102

kim@vax.mpiz-koeln.mpg.dbp.de says WORK_OUT(0) and WORK_OUT(1) - it worked

gseto@biome.bio.ns.ca suggested finding the resolution and setting a c constant at the beginning of the program after finding the resolution (low/med/high), so I guess he meant using getrez(): [The only problem I could see with this is that the Multi-TOS will not be able to accurately tell you what your boundaries in your window are with just low/med/high resolution. Plus the Falcon will have a 640x480 resolution, and we don't know what number that will be. So, for future support I'd go with finding the x,y boundaries.]

DAVEW@D.SSS.CO.UK said to use "wind_get (0,5,.....) as window 0 is the desktop."

bpat@binkley.cs.mcgill.ca said:
"Just calling open_virtual_workstation (v_openvwk) will give them to you in
ptsout(0) ans ptsout(1) (I don't know anything about Gfa, but I'm sure you can call this one)"

paul@jupiter.ame.arizona.edu said to use WORK_OUT(0), WORK_OUT(1)

==========
GFA Basic doesn't seem to enable WORK_OUT(0) and WORK_OUT(1) until after some sort of GEM call has been preformed in a compiled program. I'm speculating that this is because with a GEM function it's forced to use a appl_init() and v_openvwk() at the beginning of the program.

Any idea what the parameters are for v_openvwk()?

Thanks to everyone who responded!

3539. 80 ns SIMM's on an STE

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-20 12:50:08 UTC
From: jarleb@athena.uio.no
Message-ID: <1992Sep20.125008.27243@ulrik.uio.no>
Source record: 42741

Hi, I have a question :

I've borrowed 4 1MB SIMM's to try on my STE. Originally a 520 STE.
They were all 80 ns.

I didn't have too much time to try them out, but most of the time everything seemed to work fine.

So my question is :

Is there any known problems with these fast RAM-chips, are there
any timing problems ?

I did try the snork-demo and it worked fine, but then I tried a
few Ram-disks, and they tended to bomb out after a while.

Jarle.

I'm using 70 ns simms and have never had any problems with ram disks or other programs.

|> screen? Thanks..

Scaling in the vertical direction is easy just copy the lines of pixels the appropriate number of times.

For horizontal scaling use a look up table. Eg for 2x scaling you have a 256 entry table of words where

abcdefgh -> aabbccddeeffgghh

Or else if you have a blitter you can use the smudge bit.

Steven

3542. Modem under MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-20 19:22:49 UTC
From: mintha@geog.ubc.ca
Message-ID: <1992Sep20.192249.28309@unixg.ubc.ca>
Source record: 42749

I have a communication program that I wrote a while ago. The problem is that it runs to slow to keep up with my modem (now that I have a V.everything modem) This is especially true under MiNT. I remember Eric posting something about using Fread to read a bunch of characters from the modem port at once. This sounds like a good idea but I can't seem to get it to work.

I'm trying something like this:

```
chan=Fopen("AUX:",2);

amt_to_read=Finstat(chan);
Fread(chan,amt_to_read,buf);
```

And I can't seem to get it to work. Finstat always seems to return 1 byte to read, and Fread only sort of seems to work. What is the proper way to do this (Everything works fine using bios calls, but then I can only get 1 char at a time.) In the MiNT docs an example shows Fopen("U:/DEV/MODEM",3) What is parameter '3', my documentation doesn't show it?

Any help appreciated.
Jim

3543. JOVE for MiNT uploaded to atari.archive.umich.edu

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-20 20:25:37 UTC
From: dstailey@leidecker.gsfc.nasa.gov
Message-ID: <DSTAILEY.92Sep20152537@leidecker.gsfc.nasa.gov>
Source record: 42746
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

After about a year, I have somewhat reluctantly decided to release my port of the JOVE text editor, V.4.14.6, by uploading it to atari.archive.umich.edu. I say reluctantly, because I wish that it could have been better, but I just haven't had the time to work on it. However, I have been using this editor constantly for a year now, and so the usefulness of the JOVE environment convinced me to upload.

The good news is that all of the process control and job control features work, and that the ptys are implemented, allowing an interactive shell window. The commands for compiling and interactively linting your source code are available (M-X compile-it and M-X next-error). Other process control functions include:

shell-command (non-interactive)
i-shell-command (interactive, asynchronous, and multiple i-shell-commands run at the same time)
shell-command-to-typeout (non-interactive, doesn't send output to a text buffer, but writes directly to the screen, using
a pager)
shell (interactive shell of your choice. Make sure SHELL environment variable is set)

JOVE uses termcap, and will run from the console or under TOSWIN or MGR. The special keys are implemented (function keys, etc.), but in a kludgy way that breaks under MGR. This port would vastly benefit from the addition of MiNT's xkeys feature.

The F2 key is bound to display-bindings. F1 is the help key, and it requires that cmds.doc be in c:\jove\lib, or you will have to fix the environment.

When reporting problems, remember that I have been using JOVE for a year, and so I am aware of most of the problems. Sorry about the ^Ms showing up in all the interactive process windows. Source is provided for the adventurous. I have ifdef'd all of my modifications. getch.c is a complete rewrite, to implement the special keys. The quadruple backslashes are used in the makefile, because the lines get fed through sed. Aren't they gross?

Oh, yes, one other thing. Make sure that you use the drive u: notation when changing directories or referring to files on other drives. Otherwise, the readline emulation breaks.

Believe me, with all of it's shortcomings JOVE is still an extremely useful programming environment. Jonathan Payne did an excellent job.

(And the memory usage is minimal, especially compared with emacs.)

Doug

>>evnt_multi() dosen't always fill out the return parameters correctly. It is
>>easily reproduceable, and a known bug (also TOS 1.04)...
>>You have to call graf_mkstate() after evnt_multi() to get the correct values.
>>graf_mkstate() is much faster than evnt_multi() when doing mouse-tracking.
>
Agreed.

>Perhaps, but using graf_mkstate() and evnt_multi() in the same program
>may cause terrible problems, since evnt_multi() assumes that nobody
>collects samples of the mouse state behind its back, and will get out
>of sync if you do.
Would you also say the same for the various other graf_... calls too ? I can't believe this. Else the graf_... library apart from graf_handle and graf_mouse would be useless.

Anyway, the solution to my original question (provided by Klaus Pedersen and Peter Missel thru Email (thanks again)) is:

You must beg for the mouse with wind_update(BEG_MCTRL) before using graf_mkstate.

[Warning: the following is not proven fact]

It seems that a WHOLE lot of my problems with GEM disappeared when I started using BEG_MCTRL more lavishly, as for example `graf_dragbox' calls that got stuck, evnt_multi calls that gave inconsistent button messages over obscured windows and that didn't track mouse leavage of rectangles properly, when the mouse cursor went off into the menubar.

Nat!

3546. Text editors... for C even!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-20 22:37:40 UTC
From: landrews@outb.wimsey.bc.ca
Message-ID: <landrews.04t7@outb.wimsey.bc.ca>
Source record: 42752

With all this discussion on text editors... I have found an *excellent* text editor called Alice.

I'm not sure where it originated from and I forgot who the author was, but it has just about every feature you've ever needed.

And as long as we're talking about key commands, it uses CTRL-S and CTRL-E to start and end a block (respectively). I believe you can edit up to 6 texts at once, although there is no way to switch windows via keyboard, you must use the mouse.

There is also no word wrap available, but you CAN make it warn you (via the ST "ding") that you have gone past a certain limit (which you can set).

You can also set it to show you the time/date and/or the cursor position. But I noticed that with either of these functions on, the movement of the cursor tends to lag behind a bit (like when you hold down backspace or delete).

Anyway, I use Sozobon C, which is relatively ANSI-ish but it doesn't come with an editor, and up until now, I have had a tough time finding something I like (besides using Interlink or FzDT).

Source record: 42750

Since the floopy in my old 1040STF is dead I've to replace it!
The prices for 720kB and 1.44MB Drives are very close here so I wonder
if and how a 1.44MB drive can be connected and what modifications
have to be done! Of course these mods have to be fully compatible with
a normal drive.
Anyone knows such a modification??

Thanks a lot!!

From: tvoverbe@estwk5.estec.esa.nl
Message-ID: <BuxI3o.GDw@wm.estec.esa.nl>
Source record: 42753

I have tried to use WINX 2.0 (delivered as part of MultiGEM 2.0, also available on atari.archive.umich.edu) on my TT with UK TOS 3.06. It does start but quits with the message 'Cannot Identify GEM'. My guess is that it only works with German TOS versions. Is this correct or does anybody have it working on a non German TOS. I also tried it on my old ST with UK TOS 1.4 with the same result.

For those who do not know WINX extends the number of open GEM windows from 8 to 40 plus some other additions to GEM. Almost a must under MultiGEM with a few applications open.

There's already a set of keys which has become widely accepted: the mac conventions. The reason is because Apple was the only company around pushing their standard. They refined it and since it was good enough and certainly common enough, developers adopted it.

Atari should expand their RSC format to allow keymappings, so people can attach keys to menu items (it the application does not mess with the menus that is...)

Atari might want to create a keypad standard too, so that commands like cut paste, copy, clear, close window, cycle window, etc are at standard locations on the keypad. The functional keypad is the only thing Apollo users seem to rave about :-)

Completely agreed. Lots of proposed key-bindings in the Atari-document are
already Mac-alike, so why not let all the bindings be thus?

>Atari should expand their RSC format to allow keymappings, so people can
>attach keys to menu items (it the application does not mess with the menus
>that is...)

Hmmm, dunno.... First: if you, as a programmer, really want the shortcuts to be
user-definable, you can write your program accordingly. Do e.g. a tree-search
on the menu, find all the '^*' (=^ with a letter) strings and adapt the
key-handling routine accordingly. So a user can edit the resource to edit the
key-bindings. Or provide the user with a menu-item 'Change keys...' which gives
a dialog, etc., etc. You get the picture. On the other hand: do you really want
users to be able to mess up the key-bindings - ^S for Stop, ^Q for Quote...?
I admit that I like this freedom when working with MS-Word on the Mac, but...
Maybe the user should only be allowed to change certain bindings - like the
non-standard bindings (i.e. program specific) - while the standard bindings
like Close, Open, Quit, Print, Select All, etc., are fixed. Yeah, I kinda like
this idea myself... :)

Just my 0.00002

Me too. If I understand well enough it should be possible to write
a terminal program with two windows that addresses both the printer
and modem ports at 9600baud? That would be very interesting. I
expected something like that of Rufus, but although it supports up
to six different ports (TT) it has only one terminal window. The advantages
of a multiple system are clear if you think of a connection to a Unix
workstation. (By the way, I know something called 'uw' exists, but this
would be a lot easier.)

If only there was a function that returned the same code whenever someone
pressed the combination for e.g. SELECT ALL regardless of the type keyboard
(QUERTY, AZERTY, QWERTZ). This would immediately encourage use of standard
codes.

Hi,
It's me again. The reason for my original post was to determine whether or not I should spend some time designing in a 68030 into my 1986 vintage 1040ST. What I am hearing is that newer versions of TOS were written to deal with the stack frame differences. I assumed that Atari cared about performance and would not insert a test in front of every OS call. I guess it is a small performance hit.

Anyway What version of TOS do I need to get. I currently have the stock ROMs that came with the machine in 1986. People are hinting that 2.x will work. Does anyone know for sure. Also, in the ads, I believe that TOS 2.x comes in two chips not six. Can I just cram these into my 1040ST by converting the chip select lines to the higher order address bits needed by the denser ROMs. I know that there is a board available that will take the two ROMs and convert the addresses. But I like to solder.

Also, what version of TOS should a spend my $59 on even if I don't get around to throwing a 68030 at the ST and what are the bummers associated with some of the versions. Will my software (games, compilers, MIDI sequencers) die if I upgrade?

Bye

Hello,

before anyone else starts to spend some time in this, i have to make a
little announcement... I already did a Sun Sparc compatible /dev/audio
device driver for MiNT. It is now in the Beta test and will be freely
awailable in quite a short time (2-3 weeks).

The driver has lots of features (plays AU,WAV,VOC,RAW,AIFF, automatic
resampling if the input rate is different from the output rate, a
\pipe\audio pipe for asynchronos sound, daemon process that can be quit,
support for stereo files, sun sparc FCNTLs are supported, ATARI extension
for better sample rates...) and i also have done some ports of SUN audio
software (sox, saytime). In my 'MiNT-audio' distribution there will be some
more programs, like a CPX and TTP for configuration...

I just FTPed the speak.tar.Z package and i will put this goody into
my distribution...

Greetings, Karsten (OverScan,Berlin)

PS: I already had the phonems and looked around, where to get a
word -> phonem converter...

>non-standard bindings (i.e. program specific) - while the standard bindings
>like Close, Open, Quit, Print, Select All, etc., are fixed. Yeah, I kinda like
>this idea myself... :)

The program should refuse to run if it finds standard keycodes as specified
by Atari (or Mac, even better) replaced in the RSC. That is, a title

```
File
-------
Print ^Q
```

should be rejected, but not

```
WeirdOptions
-------
Print ^S
```

(That is, the specification should include that ^P HAS to appear in the
File menu, ^X always in the Edit menu, etc.)

It seems a waste of effort if every program would check the standard codes.
The AES already replaces the 'Desk' by the name of the application, so
why would it not be ably to get angry with programs that don't follow
the (menu-layout) rules? Of course, the problem here is that nothing
would run in such an AE. Define an RSC format that contains, say, an
optional version number; if a program wishes to be checked the version
number should be 2.0 or higher.

Just our 0.00003

(and we'd better leave it here. It's going in the wrong direction,
I fear)

Gotcha. A control panel module lets you set the keycodes for

1. A number of standard functions, defined in a c header file:

MNE_ABOUT 0
MNE_NEW 1
MNE_OPEN 2
etc.

2. A number of application-assignable functions, ordered by a
number.

You can set the codes by just pressing a key; then, the scancode as
well as the k_shift are stored, using the new function

wind_set(WF_MENUKEY,standard,number,k_code,k_shift);

Then, there is a new AES message, MN_KSELECTED with in word
(oops the # is not next to the return key) #3 the standard/user
flag and in word #4 the code itself. Programs that wish to use
the feature simply build in a routine for this message; old ST-
programs won't notice anything.

I forgot: what about the key if the program does or does not read
the message (which is rather important :\ )

>
>There's already a set of keys which has become widely accepted: the mac
>conventions. The reason is because Apple was the only company around
>pushing their standard. They refined it and since it was good enough
>and certainly common enough, developers adopted it.

I disagree with one point: the Mac keycode convention is not good enough in my opinion. Of course it is good enough for many users, that's why Apple can get along with it. But there are many computer users - myself included - who are not satisfied with it and therefore don't use Macs. (Remember that although the Mac is fairly widespread the majority of computer users still work with DOS and Windows. Of course there are also other reasons for this, but there is no statistic evidence for the claim that everyone likes Macs.)

The major shortcoming is that the convention is too limiting - there can be no more than 26 keycodes, which means that only a small subset of all commands in a big application can get one. Everything else has to be done with the mouse, which some people like and others don't.

It is a mistake to assume that just because Apple sold a lot of Macs with their conventions, Atari would sell just as many if it adopted the same conventions. After all, why should a Mac-user opt for an ST, now that Macs are no longer prohibitively expensive? Making the ST a bad Mac copy doesn't help selling it.

In my opinion Atari should provide something much more flexible than the Mac conventions. To satisfy as many potential customers as possible, keycodes should be user-configurable in a flexible manner, allowing multi-key codes of (ideally) arbitrary length, like Emacs does. Then anyone could pick his choice, whether it is Mac-compatible, WordStar-compatible, or something else. While this could be implemented in individual programs, this would be inconvenient for the user. It would be much better to have a global configuration (editable with a CPX module and stored in a public file) for all 'common' commands and additional private configurations for the specific commands of individual applications. The implementational effort would be a bit higher, but still small compared to the benefits.

I've got the impression that the NKCC package (Normalized Key Codes) that comes
with the Interface resource editor does the trick. It's a lib you can link with
your C-source. Anyone know for sure?

There actualy is a way to add more than 4 mb of memory but it involves adding
extra pins to the MMU chip and is probably more of a pain than its worth.

As far as the speed of the simms, it should not matter, the extra speed is
just wasted. If you ever decide to upgrade to ADspeed or another excelerator
they would be important but with the motorola 68000 running at 8 Mhz it is
fine. Check the ram disks you are using and maybe desk acc's.

Try: Rename (oldFileString, newFileString). This should be documented
in both your HighSpeed manual, and the online help system.

Unfortunately, no, not unless you patch the ROMs or replace the AES.
You're limited to 4 kB (actually 4192 bytes).

You might be able to alleviate the problem a bit by examining the
file with a text editor to see if there are any lines you could
delete. Sometimes, obsolete information accumulates. Also, if
a have a lot of Installed Applications deep in a folder hierarchy,
you can save a fair bit of space by moving them toward the root
(I know this is a kludge, but don't know how desparate you might
be! :-).

You should get in touch with DREAM PARK. They sell the control chip
(in Kit form) so you'll be able to use your HD drive in your ST.

3578. Re: AES bug ?

```

Since you're making calls to routines in the AES libraries (graf_xxx),
I'd consider it a good idea to initialize things first, and let the AES
know what you're doing, with appl_init.

> I also have had problems with graf_watchbox and graf_dragbox, which for
> no apparent reasons get stuck sometimes (but not predictably).

Not too surprising, for the above reason. I (and many others) have been
using these routines successfully for years, with negligible problems.

> I am writing my first real GEM program and at least in the version I
> have GEM seems to be reeking of bugs.

This remark really annoyed me, and I was going to respond with an angry
retort. But I'll restrain myself, and simply point out that it seems
rather naive to me for someone who is writing their "first real GEM
program" to describe GEM as "reeking of bugs", without considering
the quite obvious possibility that the errors may be of their own
creation.

> Apart from the most basic windowing and object redraw
> mechanisms, it appears that one has to rewrite/extend
> all of Atari/DRs code to get decent results.

While GEM does have its share of known bugs and limitations, some
minor, some rather annoying, I think it's a bit of an exaggeration
to say that each programmer has to rewrite it all to get decent
results. If this was actually true, there would be a lot less
quality applications for the ST than there are today.

I'd suggest you get a good book on GEM programming and read a bit before you jump head first into your first GEM project. You might also want to examine the source code of an existing app as an example to follow. Then you'll find the process much less frustrating, and you can get up to speed more quickly.

I've tried WINX 2.0 on U.S. ROMs for TOS 1.0, 1.2, 1.4, and 3.01.
It didn't work for any of them (which was very disappointing).
I'd really like to have the GEM window limit raised as well.
If anyone comes up with a patch to make this work, I hope they
will let us all know about it.

I have 3.0.6 and it works fine. You DID NOT specify a specific problem,
write back and be specific about preferably these points:

1) won't startup msh?
2) won't startup cc
3) any exceptions internal or otherwise.

MWC WILL NOT db itself over STE TOS's. The debugger is quite weak and
is probably just as well, you wouldn't want to use it anyway.

Yes the TOS you shoul look is 2.06 and yes it is bigger, so you need to do
a harware modification. There is quite many available, or perhaps you can
make one yourself, but do not ask me how.

>Also, what version of TOS should a spend my $59 on even if I don't get

I think in US Codehead sell a thing called TEC and it comes with TOS 2.06.

Or if you buy a ready made 68030 card I think they come also with a new
TOS (SST at least comes).

3582. RANDOM GENERATION

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-23 08:42:18 UTC
From: mark.thomas@rose.com
Message-ID: <1992Sep23.074220.8251@rose.com>
Source record: 42784

Date Entered: 09-23-92 03:36
Does anybody know how to get good random number generation using
Laser C?
My tests of the UNIX rand() function show that the odds of the
first digit being a 1 or a 2 are about 7 times greater that any other
digit.
My test of the Bios Random() function show that the odds or the
first digit being a 1 are about 7 times greater than any other digit.

Please do not ask me to access archives as it is not allowed from
this site.

From what I remember, Finstat() always returns a flag (ie., 0 or 1).
Just use

amt_read = Fread(chan, sizeof(buf), buf);

if (amt_read > 0) {
/* do neat things with the `amt_read' bytes in `buf' */

} else if (amt_read < 0) {
/* complain about read errors */
}

Dunno about Laser-specifics, but I recently downloaded a bit of source for a rand-number generator (ints and doubles I think), together with some 'utility-functions'. I haven't tried it out myself yet, but chances are good that it's much better than BIOS-rand et.al. If you're interested, email me. In fact this question belongs in comp.programming if I'm not mistaken. But who cares... :)

No ! LZH201L is the very latest, but please read the Doc's, the -k option
from memory could be the option that you need to add, with some of the older
LHA archives, as this will skip the bad headers...

Note: LZH201L will extract files with folders with out setting any options
at all, just give it the file name...

There is a new Gem/Tos function in MiNt, and with that you change the priority
of the programms. If you set your programm to highest priority, it will keep
up with the modem, else MiNT slows it down too much..

O.K.,
rand() is known to be very unrandom !
random() is much better - it just uses a simple shift-register
with feedback approach; it suffers from some regularity in low
order bits.
even better are one that are like random() but permute the bits.

I can send you Gnu sources if you like, but they may be available on your
mainframe anyway.
look at glibc_???/stdlib/{random.c,__random.c}
and AGC - the one that permutes

here follows a bit from __random.c :

(was 15k, have chopped chunks out, so don't expect it to compile as is)

The random number generation technique is a linear feedback
shift register approach, employing trinomials (since there are fewer terms
to sum up that way). In this approach, the least significant bit of all
the numbers in the state table will act as a linear feedback shift register,
and will have period 2^deg - 1 (where deg is the degree of the polynomial
being used, assuming that the polynomial is irreducible and primitive).
The higher order bits will have longer periods, since their values are
also influenced by pseudo-random carries out of the lower bits. The
total period of the generator is approximately deg*(2**deg - 1); thus

```
doubling the amount of state information has a vast influence on the
period of the generator. Note: The deg*(2**deg - 1) is an approximation
only good for large deg, when the period of the shift register is the
dominant factor. With deg equal to seven, the period is actually much
longer than the 7*(2**7 - 1) predicted by this formula. */

/* Good feed-back taps : */

/* Linear congruential. */

/* x**7 + x**3 + 1. */

/* x**15 + x + 1. */

/* x**31 + x**3 + 1. */

/* x**63 + x + 1. */

#define MAX_TYPES 5 /* Max number of types above. */

static int degrees[MAX_TYPES] = { DEG_0, DEG_1, DEG_2, DEG_3, DEG_4 };
static int seps[MAX_TYPES] = { SEP_0, SEP_1, SEP_2, SEP_3, SEP_4 };

/* Initially, everything is set up as if from:
initstate(1, randtbl, 128);
Note that this initialization takes advantage of the fact that srandom
advances the front and rear pointers 10*rand_deg times, and hence the
rear pointer which starts at 0 will also end up at zero; thus the zeroeth
element of the state information, which contains info about the current
position of the rear pointer is just
(MAX_TYPES * (rptr - state)) + TYPE_3 == TYPE_3. */

static long int randtbl[DEG_3 + 1] =

/* If we are using the trivial TYPE_0 R.N.G., just do the old linear
congruential bit. Otherwise, we do our fancy trinomial stuff, which is the
same in all the other cases due to all the global variables that have been
set up. The basic operation is to add the number at the rear pointer into
the one at the front pointer. Then both pointers are advanced to the next
location cyclically in the table. The value returned is the sum generated,
reduced to 31 bits by throwing away the "least random" low bit.
Note: The code takes advantage of the fact that both the front and
rear pointers can't wrap on the same call by not testing the rear
pointer if the front one has wrapped. Returns a 31-bit random number. */

Try and write your own:
For example something like:
(int should be 32bits long for this example)

```
int rand=674457757; //could be initialized to the current time

int nextRand(int x)
{
return x+1734329845+(x>>1);
}

void randSeed(int s)
{
rand=nextRand(s);
}

int random(int m) // m should not be too big
{
return ((rand+(rand=nextRand(rand))) >>4)%m;
}
```

A lot of other (even simpler or more complex) are
possible: just try ! (I can tell you it's fun)

>Does anyone have a clue or the same woes ?

It's absolutely normal for the ST operating system to get stuck sometimes (e.
g. when it's raining). There are some very severe bugs in the window event
handling and in graf_rubberbox(), graf_dragbox() and graf_watchbox() that
may cause a deadlock whenever you haven't saved your text. As I know these
bugs aren't fixed in newer versions of TOS, because nobody could force them
explicitely. You can try to use wind_update(BEG_MCTRL) instead of
BEG_UPDATE, than the bug should appear not so often, but you cannot write
programs that can't freeze the system.
Today the only way ist to use a TOS patch like KAOS 1.4.2B where these bugs
were fixed or an alternate operating system like the multi tasking Mag!X
where these bugs cannot appear.

>I'd consider it a good idea to initialize things first, and let the AES
>know what you're doing, with appl_init.
Ok I left this out in order to simplify the code (with hindsight this probably was too confusing), since the graf_mkstate behaves this way regardless whether you appl_init first.

>> I am writing my first real GEM program and at least in the version I
>> have GEM seems to be reeking of bugs.
>
>This remark really annoyed me, and I was going to respond with an angry

>rather naive to me for someone who is writing their "first real GEM
>program" to describe GEM as "reeking of bugs", without considering
>the quite obvious possibility that the errors may be of their own
>creation.
Well, lets put it this way. It is my first GEM program but I am not `totally naive' programmingwise. Having to enclose graf_dragbox in win_update(BEG_MCTRL) calls I would call a bug. Having graf_watchbox freeze on you I'd call a bug. Having evnt_multi calls that can't properly detect mouse leavage I'd call a bug and so on..

>While GEM does have its share of known bugs and limitations, some
>minor, some rather annoying, I think it's a bit of an exaggeration
>to say that each programmer has to rewrite it all to get decent
>results. If this was actually true, there would be a lot less
>quality applications for the ST than there are today.
Sure, I was exaggerating. Me thinks though that a lot of the quality applications you mention actually DID a whole lot of rewriting and extending to get something good going.

>I'd suggest you get a good book on GEM programming and read a bit
>before you jump head first into your first GEM project. You might
>also want to examine the source code of an existing app as an ex-
>ample to follow. Then you'll find the process much less frustrating,

Huh? I've been working/programming with my ST for several years now, and have
never encountered those 'severe bugs' you're talking about. Could you tell use
more about them, please? Esp. when they show up, of course :).
And the original poster had obviously forgotten to do an appl_init() call and a
v_opnvwk() call, as someone else noted in a previous posting, so probably
that was the problem, and not those 'severe bugs'. OK, TOS/AES/VDI could all
have been better, but they're not *that* bad.

If you have tried v2.01l of LHARC, (the one you mentioned), then you are as new as you can get.

However, the other possibility is that the file is in an OLD archive format, such as LH1 or LHA, and to extract it, you need to specify a certain flag (I don't know the exact flags, but if you have a graphics shell for it, it should be easy).

I have a 1040ST, 20 Meg HD, ICD controller (original type, not new), and an OMPTI controller (MFM).

Now, I have a friend who can get me an 80 meg IDE drive (for about $200, is this a good price?). What I need to know is if it can be used on an ST, and what extra hardware will I need. I think I recall the fact that IDE drives will not work on the SCSI chain, and I need some other controller for it. I want to know what other controller that is, and can I use an IDE drive on the ST or is it a waste of money for me.

Thanks,

Troy Carpenter

> is there some threads in MiNT or is there only processes ?

It depends on how you define "threads" (there are many conflicting definitions). MiNT allows two or more processes to share the same address space. These are "full size" processes, in a sense, but since they're running in the same address space at the same time they act in many ways like threads. The tfork() function in the MiNT library is used to start such a "thread";
tfork(function, arg)
starts a new process executing the code in the given function, with the given 32 bit argument as a parameter.

3607. Laser C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-24 14:36:06 UTC
From: carl@syscon.rn.com
Message-ID: <1992Sep24.143606.2441@syscon.rn.com>
Source record: 42710

Ok, Laser C users. Here is some hard earned information about using the debugger. The following code from an expression evaluator:

```
while ((*(*cptr++).c_operator)())
;
```

generates the following assembler:

```
000050 MOVEA.L 0xac4.L, A0
000056 ADDQ.L #0x4, 0xac4.L
00005c MOVEA.L (A0), A0
00005e JSR (A0)
000060 BNE.B 0x50
```

Note that the contition codes are expected to be preserved across the return from the fuction call. But, the following function:

```
int db_xstop()
{
return (FALSE);
}
```

generates the following assembler:

```
000000 LINK A6, #0x0
000004 PEA 0x8a6.L
00000a PEA 8(A6)
00000e JSR __dbugin.L
000014 ADDQ.L #8, A7
000016 MOVE.W #0x0, D0
00001a PEA 0x8b8.L
000020 JSR __dbugout.L
000026 ADDQ.L #0x4, A7
000028 UNLK A6
00002a RTS
```

But __dbugout does not preserve the condition codes. This makes the debugger considerably less useful.... All it takes is tst.w d0 after the jsr to fix it. Another example of sacrificing functionality for speed?

I have implemented the Cray Y-MP random number generator, which is excellent. Mine will run on any IEEE floating point compliant 32-bit architecture. There is one hitch, though. It is written in FORTRAN. A c version of it is trivial, though. I am happy to share source.

It is a 48-bit random number generator, and is linear congruential with optional large prime adders.

3612. Line A: C lib?/ bitmap manipulation on the ST..?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 04:32:01 UTC
From: wilsont@orac.holonet.net
Message-ID: <Bv49xE.1s9@iat.holonet.net>
Source record: 42726

Yes.. more questions for the tech guys..

I was wondering if there are PD C library files for the Line A routines?
or.. should I bite the bullet and learn ASM?

also, I just found out, in my TOS book, that one pixel in lowres is
spread out over 4 bytes. I have heard of this before in other architectures.
but.. Why do they do this? Isn't it slower to do it this way?

I'd like to be able to manipulate bitmaps (rotations etc) but
since the pixel info is spread out, how to I convert these types of algorithms?

i would assume that to get one pixel out of a graphics screen long word
would take 32 shifts and 4 long word masks. Am I underestimating the speed
of the 68000? it would seem that it would take a while (time that would add up
over a large bitmap) to compute.

Thanks in advance for any help.

The only "protection" SL has is that when booting, it checks the integrity
of the program file against viruses and things like that. It doesn't even
like its program flags changed.

3615. RAM upgrade question, yet another!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 05:45:34 UTC
From: reyy@vax5.cit.cornell.edu
Message-ID: <1992Sep25.014535.15069@vax5.cit.cornell.edu>
Source record: 42715

Greetings.

My apologies for asking about yet another RAM upgrade. I got
a file from atari.archive (2_5ram.zoo, I believe) and it describes
how to upgrade a 520/1040 STF/STFM to 2.5 megs. I have a
really old 520 ST here, and it only has one bank of drams
(this makes sense, right!). Anyway, the upgrade tells me to
use the upper bank to hook up some SIPs. Having an old 520ST,
I don't know how to access the upper bank. Is it a bad idea to
access the MMU directly (how could I?)? If so, does anyone
have the pinout of the MMU (I already checked, and I have the
proper MMU that can deal with 4 megs, I know that some had a
problem..)? Any recommendations?

Thanks!

3616. upload to a.a.: TOS/MiNT bindings library for Turbo/Pure C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 08:10:52 UTC
From: mh1@irz209.inf.tu-dresden.de
Message-ID: <OAC72OC@math.fu-berlin.de>
Source record: 42718
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech,de.comp.sys.st

I just uploaded an archive containing a library with TOS/MiNT bindings for Turbo/
Pure C. From the distributions README:

```
------------------------------------------------------------------------------

----------------------------------------
TOS and MiNT bindings for Turbo C / Pure C
by Ole Arndt, changes by Ulf Moeller
----------------------------------------

OSBIND.LIB fully replaces PCTOSLIB. In contrast to the original Turbo C
library, this library is reentrant. All MiNT 0.95 bindings are implemented.

This library and the assembler sources may be freely copied.

EMail:
Ole_Arndt@f.maus.de
Ulf_Moeller@hh2.maus.de

------------------------------------------------------------------------------

This library is particularly interesting for Turbo C users who want to use the
Turbo/Pure C support in the next MiNT library.

I uploaded the archive (filename: pcosbind.zoo) to the following places:

atari.archive.umich.edu
ftp.rus.uni-stuttgart.de
ftp.uni-muenster.de

The archive should make it to the respective atari/programming or atari/mint
directory soon.

If you have questions concerning the library, forward them to
ulf_moeller@hh2.maus.de.

Michael

3618. IBM 8515 monitor and STE?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 16:00:35 UTC
From: gavin@praxis.co.uk
Message-ID: <1992Sep25.160035.6928@praxis.co.uk>
Source record: 42724

Can monitors designed for PC use be used with an ST(E)?

To be more specific, I have recently acquired a used IBM 8515 colour monitor, and I would like to connect this to an STE.

I'm afraid I know very little about the monitor, other than that "it supports VGA, SVGA, XGA and 8514/A standard video". I do have details of the pin-outs on the connector attached to the monitor, so I could probably work out how to connect the two together (in principle at least!).

Can anyone who knows about these things tell me if this is worth pursuing? I suspect there's more to it than just wiring and there may be a problem with line frequencies, etc.

TIA
Gavin

3619. GNU C 2.2x available yet?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 19:32:41 UTC
From: pbh@jake.cc.wayne.edu
Message-ID: <1992Sep25.193241.1556@cs.wayne.edu>
Source record: 42721

I've been using GCC 1.4x for about a year (?) waiting to go to 2.0
when it was "safe". I just read somewhere that 2.2 is available for
the ST. If so, where? Do I keep all the same g++ libs I have
or is this a totally different beast altogether? I heard Objective
C has been rolled into the compiler in addition to the Ansi C and
C++ compilers. True? Is 2.2 more stable than 2.1?

thanks in advance for the info.

3620. Non-Blocking reads

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 20:32:33 UTC
From: cbbrowne@csi.uottawa.ca
Message-ID: <1992Sep25.203233.1046@csi.uottawa.ca>
Source record: 42723

I've got a program I'm trying to get ported to the Atari from the big wide world out there, and seem to be down to two "missing" functions:

(1) Something called kbhit(), more particularly:

```
int kbhit(void)
{ /* code omitted */
} /* This function returns TRUE if there is a key code waiting to be */
/* read, and FALSE otherwise */
```

```
(2)
int getch(void)
{
}
/* This function returns the keycode that was waiting to be read */
/* Yup, it's supposed to return an integer, not a char. That's NOT a */
/* typo. */
```

Ideally, I'd LOVE to get something that's portable between MiNT and TOS both.

There's a Unix implementation that looks like the following:

```
------Cut Here--------
#ifndef CRUDE
int kbhit(void)
/* Return TRUE if there is a key to be read */
{
#ifdef USE_SELECT /* use select() system call */
struct timeval t;
fd_set n;
int r;

timerclear(&t);
FD_ZERO(&n);
FD_SET(ttyfd, &n);
r = select(32, &n, NULL, NULL, &t);
if (r == -1) {
perror("select");
exitPGP(1);
}
return r > 0;
#else
#ifdef USE_NBIO /* use non-blocking read() */
unsigned char ch;
if (kbuf >= 0)
return(1);
```

```
if (read(ttyfd, &ch, 1) == 1) {
kbuf = ch;
return(1);
}
return(0);
#else
long lf;
if (ioctl(ttyfd, FIONREAD, &lf) == -1) {
perror("ioctl: FIONREAD");
exitPGP(1);
}
return(lf);
#endif
#endif
}
#endif /* !CRUDE */

int getch(void)
{
char c;
#ifdef USE_NBIO
while (!kbhit()); /* kbhit() does the reading */
c = kbuf;
kbuf = -1;
#else
read(ttyfd, &c, 1);
#endif
return(c);
}
-----------Ends Here------------
```

From what I can tell, this LOOKS sufficiently UNIX tty-ish that it's probably not going to be directly Atari friendly (although it's POSSIBLE with a proper redefining of "ttyfd", it might be ok).

Based on recent history, this posting is likely to actually hit the net some time in November...

3621. weird desktop with HD

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-25 23:13:48 UTC
From: osoelgaultier+@CMU.EDU
Message-ID: <0ektogu00aw90MmYo5@andrew.cmu.edu>
Source record: 42727

A friend of mine recently got an ST with 1MB (an enhanced 520STf
with TOS 2.1) and separately an even older 20MB HD from atari,
the famous SH204 !

The problem is that when he tries to use his HD, the desktop
reacts a strange way: when using text, no problem. But when
displying files as icons, some files just don't appear: the window
has 'holes' where the icon should appear but doesn't !
I tried everything: without HD or connected to another HD
(ST157N-1 with ICD adapter), no problem. But with the
SH204, a bunch of problems (the disappearing icons is
just one part of the problem. A lot of transfers are generally
erroneous)

Any idea ?

3622. how to write UNIXMODE programs?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-26 00:47:48 UTC
From: kendall@great-gray.owlnet.rice.edu
Message-ID: <KENDALL.92Sep25184748@great-gray.owlnet.rice.edu>
Source record: 42725

How does one go about writing programs that fully support UNIXMODE? I have the documnet describing the standard, but what I'd really like is some kind of C library that is ready to use. Does such a thing exist?

Thanks,

gcc 2.2.2 for ST is currently at PatchLevel 3. It was available
some two days after FSF release.

There is a series of updates on a.a which contain - among other
things Atari specific patches (not very extensive) to FSF distribution.
Look somewhere in 20'th. The last one is from August this year.
Howard Chu promissed some time ago that he will put binaries
on a.a. I do not know if they are there.

You may compile 2.x.... releases to provide compilers for C, C++
and Objective-C. This depends on compilation flags. PD-runtime
and class libraries for Objective-C are still "work in progress"
but you can go into "an experimental mode" on it.

Libraries were extensively updated (both gcc and g++). Better
get current versions.

gcc 2.2.2 still may trip you. It happens. Expect 2.3 RSN.
On the other hand I compiled with it many programs (on ST and
other machines) and they work without a hitch. It compiles,
in particular, itself. I wish if some commercial compilers would
be as stable as this beta release.

Just put 'em up tonight. Go get gnustuff/tos/gcc/gc222bin.zoo and
gnustuff/tos/gnulib/gc222lib.zoo.

The bin archive contains the compiler (gcc 2.2.2, patchlevel 3 +
my changes), assembler (gas 1.38.1 patchlevel 3 + my fix), linker
(patchlevel 31 + my changes) and other associated utilities.

The gc222lib archive contains binaries for the library as well as
the full set of include files. Also, the library is actually built
from the MiNT library, patchlevel 21 plus some of my changes.
Mintlib21 corresponds pretty much with the GNU library patchlevel 83.

Note that my changes haven't yet come back in an official patch
set so this is a very informal, unofficial distribution. I've
been using it myself without trouble, so you should expect to be
able to use it as well, but you might want to wait for the next
official set of patches and such.

>You may compile 2.x.... releases to provide compilers for C, C++
>and Objective-C. This depends on compilation flags. PD-runtime

>but you can go into "an experimental mode" on it.

I didn't build the C++ or Objective-C compilers this time 'round.
>
>Libraries were extensively updated (both gcc and g++). Better
>get current versions.

Yep. The TOS and MiNT libraries are getting closer and closer to being totally merged. *** Huge thanks to Jwahar Bammi and Eric Smith for all the great work they've been doing. *** I have a lot of fun playing with this stuff but only because they've done so much to make everything so powerful and easy to use.

The binaries in these two archives support base-relative addressing for static and global variables, which can be used to create shared-text programs. Under MiNT 0.96, multiple invocations of a program will run from a single copy of the code/text, if the program is marked as sharable. See the Readme file in the bin archive for more info.

Btw, gc222bin.zoo is about 590K, gc222lib.zoo is about 350K.

At least one of the variants of code you posted would work under MiNT
with the MiNT library (MiNT supports ioctl(FIONREAD,...) and all
of the other common Berkeley ioctl() functions). It wouldn't work
under plain TOS, though.

If you're willing to have the code work only on the console,
you could probably do something like:

```
int kbhit() { return Bconstat(2); } /* is a character waiting */
int getch() { return Bconin(2) & 0x00ff; } /* read 1 character */
```

This will work under both TOS and MiNT.

3626. Xircom Ethernet Adapter Software

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-26 18:06:55 UTC
From: bkr@drdhh.hanse.de
Message-ID: <1992Sep26.180655.3208@drdhh.hanse.de>
Source record: 42734

I heard rumours that there exists a Xircom Ethernet Adadpter
driver for the Atari ST.

(That's the little box you plug into your PC printer port)

If anybody can tell me about the existance and/or location
availability/price for this software or can give me any
address of anybody associated with it, it'd be appreciated.

Please mail answers, I'll post a summary if there is enough
request - otherwise I'll forward responses to interested people.

Thanks for your audience,
Bjoern

hello people !

i've got a question for you cracks...
i have a vortex HD with 20MB which i want to replace bye a bigger
one (only the drive, not what's around).
so my questions are:
there are two platines one is by vortex, but what's the other one
for ? what does it control ?
has anybody any suggestions as what kind of drive i should
put in ?

any suggestion is welcome...

>There's a Unix implementation that looks like the following:
>------Cut Here--------
```

Ah, looks like you're porting from MSDOS... On the ST, the GEMDOS function Cconis() will serve for kbhit(), it returns true/false depending on if there is a character available on the console, and Cconin will read 1 character. Cconin returns a long (not just an int) with the high word containing the keyboard scan code of the character read. You can get more info on the GEMDOS calls from most ST programming books. (It also sounds like you're not using any ST programming books in your current effort, otherwise you might have bumped into this solution already... It would be a good idea to get hold of some real documentation before you proceed any further...)

Since MiNT is backward compatible with TOS, you'll be pretty safe using these GEMDOS functions with either TOS or MiNT. Also you should note that these GEMDOS functions can have their target devices redirected, e.g. someone starting up your program can decide to point Ccon at the RS232 port and your program will work using the serial port instead of the console, and all of that is transparent to you... (i.e., you don't have to do anything special to make it work).

Finally, you should be careful about how you do I/O in this program. As an example, in Unix you can use the stdio library (printf, putchar, getchar, etc.) or you can call the Unix system directly (read, write, lseek, etc.). The stdio library is built with the Unix system calls, but adds its own layer of buffering between your program and the system. On the ST you have the same situation, but with several more possible levels of indirection. Most C compilers for the ST come with an ANSI/Unix-style library, which will include an stdio implementation. They will also include Unix read/write/lseek emulation, but now you have to realize that both stdio and read/write are library level, and the actual "system level" is one level deeper, at the GEMDOS function level. In fact, for functions like getting a character from a tty-style device, there's yet another lower layer, the BIOS level. Unix programming manuals warn you not to mix stdio calls with system calls, because the stdio buffering will get fouled up when you go directly to the system. You have to keep this mind on the ST as well, and realize that you have to make sure not to mix up any of BIOS, GEMDOS, read/write, or stdio. Every level of that list provides its own buffering, so mixing calls between them is definitely a bad idea.

(Actually, whether or not the read/write emulation does any buffering varies depending on whose C library you use. As I think about it, most of them simply translate this set of Unix system calls directly to their GEMDOS equivalents.)

The main point of this spiel is to make sure you choose only one level of I/O routines to use, and stick with it. If you really know what you're doing you can mix and match, but it's a real pain when you get it wrong.

Usually when I port stuff I tend to use GEMDOS level or higher, that way the programs will behave properly when run from the console or run remotely over the serial port.

If you're using GNU C you can just use the linea.h that's provided in the
GCC C library. As far as I know, Turbo C also comes with linea bindings.
MWC does as well.
>
>also, I just found out, in my TOS book, that one pixel in lowres is
>spread out over 4 bytes. I have heard of this before in other architectures.
>but.. Why do they do this? Isn't it slower to do it this way?

Just a function of how they decided to design their video hardware. First of
all, remember that you're working with a 16-bit architecture, not 8-bit. That
means you can grab 16 bits at a time on every memory reference, so there's no
efficiency gain in using byte-oriented data.

The video hardware is built around a chip known as SHIFTER. This chip is so
named because that's exactly what it does; instead of writing a word of
video data to the screen all at once, it grabs the data for 16 pixels at a time
and shifts them out to the screen one pixel at a time. E.g., ST lo-res:

```
word-1 word-2 word-3 word-4 -> word-1
word-2
word-3
word-4
^
|__ 4 bits at a time are peeled
off to form the palette index
```

>I'd like to be able to manipulate bitmaps (rotations etc) but
>since the pixel info is spread out, how to I convert these types of algorithms?
>
>i would assume that to get one pixel out of a graphics screen long word
>would take 32 shifts and 4 long word masks. Am I underestimating the speed
>of the 68000? it would seem that it would take a while (time that would add up
>over a large bitmap) to compute.

Hm. 4 longword masks? I don't see why that would be, you can simply load one
byte at a time. Actually, you can do it really easily with the movep
instruction. Point an address register at the byte containing the first bit
of the pixel you want, use movep to load the pixel bytes into a register,
shift once to get the right orientation, get the even bits, shift again by 8,
and get the odd bits. Like so:

```
/* nothing like real code for examples, eh? */
/* Copyright 1992 by Howard Chu. You may use this code in
your programs provided that you acknowledge the source. */

int
getpixel (int x, int y) /* assumes lo-rez. med-rez is even easier */
{
register char *addr __asm__("a0");
register long pixdat __asm__("d1");
register int result __asm__("d0");
register int shift __asm__("d2");

addr = screenbase + y * bytes_per_row + x/2;
shift = x & 7;
result = 0;

time __asm__("
24 movepl a0@,d1 /* get pixel data */
8-22 lsll d2,d1 /* shift left to desired bit */
8-10 jpl 0f /* first bit is now in sign bit - check it */
4 moveq #1,d0
4 0: tstw d1 /* 3rd bit is word sign-bit - check it */
8-10 jpl 1f
4 addqw #4,d0
24 1: lsll #8,d1 /* shift 2nd and 4th bits into place */
8-10 jpl 2f /* 2nd bit is sign bit - check it */
4 addqw #2,d0
4 2: tstw d1 /* 4th bit is word sign-bit - check it */
8-10 jpl 3f
4 addqw #8,d0
3:");
return(result);
}
```

There ya have it, no longword masks, and only two shift instructions. Piece of cake, and valid GNU-C, t'boot. You can easily convert this into a loop to decode a block of 16 pixels at a time. For medium rez, you only need to do a word-length movep. As a further optimization, you can precompute a table of row_addresses to save time when calculating the initial addr to use.

Total execution time for the marked code is 104 to 126 cycles, best to worst case. (Might actually be 112 best case, I think the 10 cycle branches will get padded to 12 by the bus timing.) That amounts to 13 to 15 microseconds per pixel, running at 8MHz. To convert an entire screen would spend just about 880 milliseconds in this code, best case, to just over 1 second, worst case. Doesn't seem too bad.

The post looks okay when reading but when replying the lines are definitely
longer than 80 characters. I've noticed this on some posts from Germany as
well. As for what causes it, I have no idea.

Where are these update-files? I just can find the files until update20.zo
(atari/gnustuff/tos/updates) and they are to build gcc2.1 and old versions of
the libs.
Thanks,

I do not know any controllers that convert SCSI to IDE and I think it
would be much better for you to look for a SCSI drive. I think you should
find a 80-100 MB SCSI drive for $200-300, but I not know the prices there.

Can I use these calls within a VBI? I have already tried it and get reboots. I think what might be happening is that the interrupt occurs after the system writes the GI select register but before it does the access so by the time my VBI is done, the GI select register no longer contains the value the system wrote to it. In the developer docs it says bios calls (trap #14) are O.K. in interrupt service routines.

Any help would be greatly appreciated.

PLEASE, do NOT use the Line-A functions, they are lowlevel VDI-driver
functions, and shouldnt be used by other programs. Imagine a ST with a
graphics board, what memory layout does it use for the screen?
Instead, use the appropriate VDI functions, they will work even with
wierd graphics cards, if there is a VDI driver for that card.
The VDI has functions to copy and transform rasters, so use these for
your purpose.

Since there are at least three company making SCSI Ethernet device, a driver for the SCSI Ethernet would be nice. The company that I know of only has the driver for PC and Mac.

These SCSI Ethernet boxes are external and connect to the SCSI port. They do work, at least with Mac as we have four of these boxes working with Mac (from SE to Mac II). Cost is ranging from $250 to $400. And maybe less for higher education.

In principal, with a SCSI device driver and recompile the NCSA Telnet on a ST should work.[No, I don't know how to write a SCSI device driver]

Just some information.

3645. Haba harddisk software?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-28 19:05:35 UTC
From: winfrvk@dutiws.tudelft.nl
Message-ID: <2136@dutiws.tudelft.nl>
Source record: 42651

Hello all,

A friend of mine has an old HABA harddisk for his ST. The original drive
mechanism was 10Mb, but that one has crashed, and was replaced by a 20Mb
drive.
The problem is: The program to format the drive doesn't have any options,
it's just double-click and it formats 10Mb. This works, but we would like
to use the other half of the diskspace as well.

The question: Does anyone have a version of the haba-software which can
format a 20Mb disk?
If no other version of the software exists, does anyone know if I can use
an old SH204 DMA->SCSI adapter in place of the one that I presume is in
the haba-box?

I hope someone remembers this beast, otherwise I'l have to ask in
alt.folklore.computers, and I don't know if that says something good or bad
about the ST. ;-)

There is one one problem with this.. to get any image on the screen with any speed you have to generate a raster image in memory before you use VDI to display it.. you then need to know the screen format! If only there were a simple 24bit standard image format which VDI interpreted and displayed :-).

Even better would be a 32 bit image format, byte order being RGBA where R = red channel, G = green channel, B = blue channel and A = Alpha channel. :-)

Those files seem to have disappeared. I sent them again today. Btw, the
file renaming has occurred, so now you can find things in
~ftp/atari/Gnustuff/Tos/Updates

I've put updates 21-24 up, which is the latest official collection.
The gc222bin and gc222lib stuff that I put up is based on update24 +
additional changes...

Oh, God. Pleeeeeease, nobody do this!
We have one of those "wonderful" NeXT printers in the lab, and whenever
it starts whining at us, it's met with a chorus of "SHUT UP!"s from anyone
near it.
Beeps, pings, clicks, and whistles are fine for alerts, and can be sampled
and used by someone to their heart's content, but in my experience talking
appliances are just annoying.

3652. Cyber Seq. Info and Question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-29 06:16:55 UTC
From: plate@cdsmn.mn.org
Message-ID: <BvBtG9.958@cdsmn.mn.org>
Source record: 42659

Hi,
I started messing around with some picture formats over the weekend.
I wrote a small program to display PI1 format and then began to hack away
at the Cyber Seqence animation format. This is my first attempt at ST
graphics.

First the information: The picture format document that I got from
atari archive was inaccurate in it's description of the Cyber Sequence
format. At least with regard to the three .seq files that I have
(klingone.seq, scanned.seq and lamp.seq). After the initial sequence
header, as described in the document, there is an array of longs that
make up a frame index (this is not in the document).
There is one long (32 bit) word for each frame
of the sequence. Each of these words is an offset into the sequence file
pointing to the frame headers. After this frame index begins the frame
headers and data as described in the document. I was able to figure this
out using a hex file editor.

Now the question: I am having a little trouble understanding how the image
data is packed. The runlength style encoding I understand, it's the splitting
up of the bit planes that I'm having trouble with. My confusion has to do
with the terminology used to descibe the bit planes. The document says
the four bitplanes are split up and written vertically:

bitplane 0, word 0, scanline 0
bitplane 0, word 0, scanline 1
...
bitplane 0, word 0, scanline 199 (assuming 200 scanlines)
bitplane 0, word 1, scanline 0
etc.

How are the bitplanes numbered? What does it mean "word 0" , "word 1"?

I understand that it takes bits from four words to make a pixel. Assuming
these four words are numbered 0, 1, 2, 3, isn't bitplane zero for the
sixteen associated pixels all located in word zero?

Help!

Regards,
Doug Sr.

>picture??

Most likely, you have a bad cable and the pin carrying the red signal has
come loose. That happened on one of my monitor cables, had to take the 13-pin
plug apart and re-solder it. (God I hated that. It's a real bitch getting in
there between the other wires...)

I did give this some thought. You're absolutely right you'd better not
replace all alerts by spoken ones without allowing the user to disable
this feature. One possibly interesting idea is the following: when you're
using, say, a text editor (I'm sorry...) and the application senses it's
soon going to be out of memory (but not entirely) it could give you
a spoken message while you go on typing. All spoken messages should be
warnings or compliments rather than failure reports. If spoken messages,
like with the NeXT printer, get too much associated with `there is something
completely wrong' then obviously they will only get irritating in the end.

3655. monitor burned away.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-29 09:38:27 UTC
From: ramaer@cs.utwente.nl
Message-ID: <1992Sep29.103827@cs.utwente.nl>
Source record: 42660

Yesterday my monitor started smoking (while I am a non-smoker).
Does anyone know if it is possible to attach a normal monitor
that takes a compisite video signal to an atari?
I have a spare monitor from the old days when I had an apple II, and
if I remember correctly it accepts 1 V top-top at 8 ohm.

I have some docs that say that the signals on the video connector
are divided into horizontal sync, vertical sync and monochrome.
Probably I will have to merge these into one signal but my question
is: how?

I am not afraid of a soldering iron.

Any help is appreciated,
Mark Ramaer

>near it.
I did give this some thought. You're absolutely right you'd better not
replace all alerts by spoken ones without allowing the user to disable
this feature.

However, as a home computer user, I often walk away from a busy machine to another room. Having the ability for the machine to tell me something finished or that something is wrong is useful. Especially useful is the ability to distinquish between something completing, that I do not need to attend to, and a problem (out of paper) that I may wish to attend to quickly.

Such a feature MUST be selectable. On my GCR I have Trek sounds on some functions and although it is OK during the day, persons trying to sleep are REALLY irritated by the noise (:-)

If you have your ST's owner's manual, take a look in the
back. There are pinouts for all ports including the video port.
What you will want to use are the pins labeled: Ground, and
General Purpose output<---(this is a composite video out!)
the only problem is trying to find a 13 pin DIN connector. I
once heard that it was possible to cut a standard PC board from
Radio Snack to size and solder some wires onto it as pins, but
this you must try at your own risk. My local ST dealer was able
to provide me with the 13 pin DIN, so you might check that out
first.
You might use a VCR to connect your ST to a TV set.
admitedly this is the poorest picture, but if all else fails...

Message-ID: <1aaa7clNN8qq@usenet.INS.CWRU.Edu>
Source record: 42664

I have an Amiga 500 that a friend of mine gave to me.
I've been using the mono video out on the back, but this is
BORING! Does anyone know if I can connect my ST's monitor to the
Amiga's analogue RGB out? The Amiga, I am told, has a Horiz.
sync signal at 15.7 Khz. Will this work with the ST's monitor.
I am also aware that the ST's monitor is an analogue RGB type.
Sounds good. Right? Let me know if I am mistaken or misinformed.

From: dumgrunt@ccwf.cc.utexas.edu
Message-ID: <80750@ut-emx.uucp>
Source record: 42670

Does anyone know the pinouts for the 6-chip TOS ROMs? I want to make a board that will let me mount and switch between two different ROM sets. I know it sounds strange, but there are a few quirks in TOS 1.0 that I actually want to use from time to time. From what I've seen, there's a "chip enable" pin that should let me toggle between the two sets with a simple double throw switch. If I'm right, and you know which pin is which, please let me know. If I'm wrong, please let me know also. :-)

From: svleest@handel.crhc.uiuc.edu
Message-ID: <1aaes7INNnbf@roundup.crhc.uiuc.edu>
Source record: 42669

Can anyone give me a brief overview of how to write a printer driver, or point me to a source of info on this topic? I can dump the screen image to my particular printer (converting the screen bit image to something my printer understands), but I assume there is a better way to do it. My method is limited to what is displayed on the screen. I would like to be able to do vdi routines to some buffer area and then dump this to the printer.

Any help would be greatly appreciated...

3667. Answer, with source code (was Re: Cyber Seq. Info and Question)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-29 22:04:20 UTC
From: dmb@pf.ai.mit.edu
Message-ID: <28601@life.ai.mit.edu>
Source record: 42671

In article <BvBtG9.958@cdsmn.mn.org> plate@cdsmn.mn.org (Doug Plate) writes:
>First the information: The picture format document that I got from
>atari archive was inaccurate in it's description of the Cyber Sequence
>format.

Correct. Thanks for pointing this out. I looked at my Cyber loading
code and found the following:

```
/*
* Check magic to ensure that this is really a .SEQ file
*/
if (sheader.magic != MAGIC1 && sheader.magic != MAGIC2) {
diag(MYNAME, eCORRUPT);
goto Bailout;
}

/*
* Skip over frame offset information
*/
len = sheader.cel_count * 4;
if (Fseek(len, fd, 1) < 0) {
diag(MYNAME, eREAD);
goto Bailout;
}
```

The fact that the offset data is useless may have been the reason I
forgot to mention it in the document. Oops. (For those of you who are
wondering why it's useless, consider that every frame depends on the
previous one, which depends on the previous one, etc.; so you have to
access the frames sequentially regardless of whether you have offsets.)

I'll post the corrected documented in the next message.

>Now the question: I am having a little trouble understanding how the image
>data is packed. The runlength style encoding I understand, it's the splitting
>up of the bit planes that I'm having trouble with. My confusion has to do
>with the terminology used to descibe the bit planes. The document says

> bitplane 0, word 0, scanline 199 (assuming 200 scanlines)
> bitplane 0, word 1, scanline 0
> etc.
>

>How are the bitplanes numbered? What does it mean "word 0" , "word 1"?

ST low res screen ram is has four bitplanes. Consider the first 16
pixels of scanline one (i.e., the 16 pixels that are in the upper
left corner of the screen). Screen memory for these is laid out as
follows:

bitplane 0, word 0
bitplane 1, word 0
bitplane 2, word 0
bitplane 3, word 0

The next 16 pixels look like this:

bitplane 0, word 1
bitplane 1, word 1
bitplane 2, word 1
bitplane 3, word 1

etc. There are 80 words per line total, yielding 20 words per bitplane.

What the description above is trying to say is this: you get the data
a bitplane at a time (unlike the ST screen ram, which packs the
bitplanes together), and in vertical columns (again, unlike the ST,
which stores the screen RAM in horizontal rows).

The reason for the translation is that you get much better compression
when you separate the bitplanes and process them vertically.

>I understand that it takes bits from four words to make a pixel. Assuming
>these four words are numbered 0, 1, 2, 3, isn't bitplane zero for the
>sixteen associated pixels all located in word zero?

Yes, but that's the format of ST screen RAM. The format of the
uncompressed data is not the same.

I've included assembly source to convert the data from the format
above to the ST screen RAM format. Use it in good health.

Introductory Information
----
word = 2 bytes
long = 4 bytes
palette = Hardware color palette, stored as 16 words. First word is
color register zero (background), last word is color register
15. Each word has the form:

Bit: (MSB) 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00 (LSB)
-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --
0 0 0 0 0 R2 R1 R0 0 G2 G1 G0 0 B2 B1 B0

R2 = MSB of red intensity
R0 = LSB of red intensity

G2 = MSB of green intensity
G0 = LSB of green intensity

B2 = MSB of blue intensity
B0 = LSB of blue intensity

Intensity ranges from 0 (color not present) to 7 (highest
intensity).

Example: { red = 7, green = 3, blue = 5 } -> 0735 (hex)

Caveat: It is wise to mask off the upper four bits of each
palette entry, since a few programs store special
information there (most notably Art Studio).

The Formats

<NEOchrome> *.NEO

1 word flag byte [always 0]
1 word resolution [0 = low res, 1 = medium res, 2 = high res]
16 words palette
12 bytes filename [usually " . "]
1 word color animation limits. High bit (bit 15) set if color
animation data is valid. Low byte contains color animation
limits (4 most significant bits are left/lower limit,
4 least significant bits are right/upper limit).
1 word color animation speed and direction. High bit (bit 15) set
if animation is on. Low order byte is # vblanks per step.
If negative, scroll is left (decreasing). Number of vblanks
between cycles is |x| - 1
1 word # of color steps (as defined in previous word) to display
picture before going to the next. (For use in slide shows)
1 word image X offset [unused, always 0]
1 word image Y offset [unused, always 0]
1 word image width [unused, always 320]
1 word image height [unused, always 200]
33 words reserved for future expansion
16000 words picture data (screen memory)

32128 bytes total

<NEOchrome Animation> *.ANI

NOTE: To get this feature on versions 0.9 and later select the Grabber
icon and click both mouse buttons in the eye of the second R in the
word GRABBER.
Interestingly enough, some versions of NEO only require you
to press the right button, not both. Hmmm...

1 long magic number BABEEBEA (hex) (seems to be ignored)
1 word width of image in bytes (always divisible by 8)
1 word height of image in scan lines
1 word size of image in bytes + 10 (!)
1 word x coordinate of image (must be divisible by 16) - 1
1 word y coordinate of image - 1
1 word number of frames
1 word animation speed (# vblanks to delay between frames)
1 long reserved; should be zero
----
22 bytes total for header

? words image data (words of screen memory) for each frame, in
order

<DEGAS> *.PI1 (low resolution)
*.PI2 (medium resolution)

*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)

32034 bytes total

<DEGAS Elite> *.PI1 (low resolution)
*.PI2 (medium resolution)
*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)
4 words left color animtion limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag (0 = left, 1 = off, 2 = right)
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

32066 bytes total

<DEGAS Elite (Compressed)> *.PC1 (low resolution)
*.PC2 (medium resolution)
*.PC3 (high resolution)

1 word resolution (same as Degas, but high order bit is set;
i.e., hex 8000 = low res, hex 8001 = medium res,
hex 8002 = high res). Other bits may be used in the
future; use a simple bit test rather than checking
for specific word values.
16 words palette
< 32000 bytes control/data bytes
4 words left color animation limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag [0 = left, 1 = off, 2 = right]
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

< 32066 bytes total

Compression Scheme:

PackBits compression is used (see below). Each scan line is compressed
separately; i.e., all data for a given scan line appears before any data
for the next scan line. The scan lines are specified from top to bottom
(i.e., 0 is first). For each scan line, all the data for a given bit plane

appears before any data for the next higher order bit plane. Note that this is identical to the IFF 'BODY' image data.
To clarify: The first data in the file will be the data for the lowest order bit plane of scan line zero, followed by the data for the next higher order bit plane of scan line zero, etc., until all bit planes have been specified for scan line zero. The next data in the file will be the data for the lowest order bit plane of scan line one, followed by the data for the next higher order bit plane of scan line one, etc., until all bit planes have been specified for all scan lines.

Caveats:

DEGAS Elite's picture loading routine places some restrictions on compressed DEGAS files:

o Elite uses a 40-byte buffer to store data being decompressed.

o Whenever a control command is encountered, bytes are stuffed in this buffer.

o The buffer is only emptied when there are EXACTLY 40 characters in it.

The important conclusion here is that

No control command may cause the buffer to have more than 40 bytes in it. In other words, all control commands must end on or before the 40-byte boundary.

Any picture violating the last condition will cause Elite to get a bus error when the picture is loaded.

<Tiny> *.TNY (any resolution)
*.TN1 (low resolution)
*.TN2 (medium resolution)
*.TN3 (high resolution)

Several people have reported sightings of mutated Tiny pictures that do not follow the standard format, so let's be careful out there. What is described here is the format that David Mumper's original TNYSTUFF.PRG produces.

1 byte resolution (same as NEO, but +3 indicates rotation information also follows)

If resolution > 2 {
1 byte left and right color animation limits. High 4 bits hold left (start) limit; low 4 bits hold right (end) limit
1 byte direction and speed of color animation (negative value indicates left, positive indicates right, absolute value is delay in 1/60's of a second.
1 word color rotation duration (number of iterations)
}

16 words palette
1 word number of control bytes
1 word number of data words
3-10667 bytes control bytes
1-16000 words data words

42-32044 bytes total

Control byte meanings:

For a given control byte, x:

x < 0 Absolute value specifies the number of unique words to
take from the data section (from 1 to 127)
x = 0 1 word is taken from the control section which specifies
the number of times to repeat the next data word (from
128 to 32767)
x = 1 1 word is taken from the control section which specifies
the number of unique words to be taken from the data
section (from 128 - 32767)
x > 1 Specifies the number of times to repeat the next word
taken from the data section (from 2 to 127)

Format of expanded data:

The expanded data is not simply screen memory bitmap data; instead, the
data is divided into four sets of vertical columns. (This results in
better compression.) A column consists of one specific word taken
from each scan line, going from top to bottom. For example, column 1
consists of word 1 on scanline 1 followed by word 1 on scanline 2, etc.,
followed by word 1 on scanline 200.
The columns appear in the following order:

1st set contains columns 1, 5, 9, 13, ..., 69, 73, 77 in order
2nd set contains columns 2, 6, 10, 14, ..., 70, 74, 78 in order
3rd set contains columns 3, 7, 11, 15, ..., 71, 75, 79 in order
4th set contains columns 4, 8, 12, 16, ..., 72, 76, 80 in order

Note that Tiny partitions the screen this way regardless of resolution; i.e.,
these aren't bitplanes. For example, medium resoltion only has two bitplanes,
but Tiny still divides medium resolution pictures into four parts.

<Spectrum 512> *.SPU

80 words first scan line of picture (unused) -- should be zeroes
15920 words picture data (screen memory) for scan lines 1 through 199
9552 words 3 palettes for each scan line (the top scan line is
not included because Spectrum 512 can't display it)

51104 bytes total

Note that the Spectrum 512 mode's three palette changes per scan
line allow more colors on the screen than normally possible, but a
tremendous amount of CPU time is required to maintain the image.

The Spectrum format specifies a palette of 48 colors for each scan line.
To decode a Spectrum picture, one must be know which of these 48 colors
are in effect for a given horizontal pixel position.

Given an x-coordinate (from 0 to 319) and a color index (from 0 to 15),
the following C function will return the proper index into the Spectrum
palette (from 0 to 47):

```
/*
* Given an x-coordinate and a color index, returns the corresponding
* Spectrum palette index.
*
* by Steve Belczyk; placed in the public domain December, 1990.
*/
int
FindIndex(x, c)
int x, c;
{
int x1;

x1 = 10 * c;

if (1 & c) /* If c is odd */
x1 = x1 - 5;
else /* If c is even */
x1 = x1 + 1;

if (x >= x1 && x < x1 + 160)
c = c + 16;
else if (x >= x1 + 160)
c = c + 32;

return c;
}
```

<Spectrum 512 (Compressed)> *.SPC

```
1 word flag word [$5350 or "SP"]
1 word reserved for future use [always 0]
1 long length of data bit map
1 long length of color bit map
<= 32092 bytes compressed data bit map
<= 17910 bytes compressed color bit map
--------------
<= 50014 bytes total
```

Data compression:

Compression is via a modified run length encoding (RLE) scheme,
similar to DEGAS compressed and Tiny. The data map is stored as a
sequence of records. Each record consists of a header byte followed by
one or more data bytes. The meaning of the header byte is as follows:

For a given header byte, x:

0 <= x <= 127 Use the next x + 1 bytes literally (no repetition)
-128 <= x <= -1 Use the next byte -x + 2 times

The data appears in the following order:

1. Picture data, bit plane 0, scan lines 1 - 199
2. Picture data, bit plane 1, scan lines 1 - 199
3. Picture data, bit plane 2, scan lines 1 - 199
4. Picture data, bit plane 3, scan lines 1 - 199

Decompression of data ends when 31840 data bytes have been used.

Color map compression:

Each 16-word palette is compressed separately. There are three
palettes for each scan line (597 total). The color map is stored as a
sequence of records. Each record starts with a 1-word bit vector which
specifies which of the 16 palette entries are included in the data
following the bit vector (1 = included, 0 = not included). If a palette
entry is not included, it is assumed to be zero (black). The least
significant bit of the bit vector refers to palette entry zero, while the
most significant bit refers to palette entry 15. Bit 15 must be zero,
since Spectrum 512 does not use palette entry 15. Bit 0 should also be
zero, since Spectrum 512 always makes the background color black.
The words specifying the values for the palette entries indicated in
the bit vector follow the bit vector itself, in order (0 - 15).

NOTE: Regarding Spectrum pictures, Shamus McBride reports the following:

"... [The Picture Formats List] says bit 15 of the color map vector
must be zero. I've encountered quite a few files where [bit 15] is
set (with no associated palette entry)..."

<Spectrum 512 (Smooshed)> *.SPS

This format compresses Spectrum 512 pictures better than the standard
method. There are at least two programs that support this format, SPSLIDEX
and ANISPEC, although the two seem to differ slightly in their interpretation
of the format.
One point of interest: Shamus McBride deciphered this format without an ST!

1 word 5350 (hex) ("SP")
1 word 0 (reserved for future use)
1 long length of data bit map
1 long length of color bit map
<= ? bytes compressed data bit map
<= ? bytes compressed color bit map

< ? bytes total

Data compression:

Compression is via a modified run length encoding (RLE) scheme,
similar to that used in Spectrum Compressed (*.SPC) pictures.

The data map is stored as a sequence of records. Each record consists of a header byte followed by one or more data bytes. The meaning of the header byte is as follows:

For a given header byte, x (unsigned):

0 <= x <= 127 Use the next byte x + 3 times
128 <= x <= 255 Use the next x - 128 + 1 bytes literally
(no repetition)

There are two kinds of *.SPS files.

The data may appear in the same order as *.SPC files (SPSLIDEX format?):

1. Picture data, bit plane 0, scan lines 1 - 199
2. Picture data, bit plane 1, scan lines 1 - 199
3. Picture data, bit plane 2, scan lines 1 - 199
4. Picture data, bit plane 3, scan lines 1 - 199

The second variant (ANISPEC format?) encodes the data as byte wide vertical strips:

Picture data, bit plane 0, scan line 1, columns 0 - 7.
Picture data, bit plane 0, scan line 2, columns 0 - 7.
Picture data, bit plane 0, scan line 3, columns 0 - 7.
. . .
Picture data, bit plane 0, scan line 199, columns 0 - 7.
Picture data, bit plane 0, scan line 1, columns 8 - 15.
Picture data, bit plane 0, scan line 2, columns 8 - 15.
. . .
Picture data, bit plane 0, scan line 199, columns 312 - 319.
Picture data, bit plane 1, scan line 1, columns 0 - 7.
. . .
Picture data, bit plane 3, scan line 198, columns 312 - 319
Picture data, bit plane 3, scan line 199, columns 312 - 319.

A for loop to process that data would look like

```
for (plane = 0; plane < 4; plane++)
for (x = 0; x < 320; x += 8)
for (y = 1; y < 200; y++)
for (x1 = 0; x1 < 8; x1++)
image[y, x + x1] = ...
```

Color map compression:

Color map compression is similar to *.SPC color map compression, but the map is compressed as a string of bits, rather than words. There are 597 records (one for each palette). Each record is composed of a 14-bit header followed by a number of 9-bit palette entries. The 14-bit header specifies which palette entries follow (1 = included, 0 = not included). The most significant bit of the header refers to palette entry 1, while the least significant bit refers to palette 14. Palette entries 0 and 15 are forced to black (zero). Each palette entry is encoded as "rrrgggbbb".

The format of the palette is described above in the section on uncompressed
Spectrum pictures (*.SPU).

<Art Director> *.ART (low resolution only)

16000 words picture data (screen memory)
16 words palette
15 * 16 words 15 more palettes for animation

32512 bytes total

<C.O.L.R. Object Editor Mural> *.MUR (low resolution only)

16000 words picture data (screen memory)
(palettes are stored in separate files)

32000 bytes total

<Doodle> *.DOO (high resolution only)

16000 words picture data (screen memory)

32000 bytes total

<Cyber Paint Sequence> *.SEQ (low resolution only)

This format, while fairly complex, yields excellent compression of animated
images while offering reasonably fast decompression times.

1 word magic number [$FEDB or $FEDC]
1 word version number
1 long number of frames
1 word speed (high byte is vblanks per frame)
118 bytes reserved
----
128 bytes total for .SEQ header

for each frame {

1 word width of this frame, in pixels (may be 0, see below)
1 word height of this frame, in pixels (may be 0, see below)
1 byte operation [0 = copy, 1 = exclusive or]
1 byte storage method [0 = uncompressed, 1 = compressed]

1 long length of data in bytes (if the data is compressed, this
will be the size of the compressed data BEFORE decompression)
60 bytes reserved
----
128 bytes total for frame header

? bytes data
}

Frames are "delta-compressed," meaning that only the changes from one frame to the next are stored. On the ST, .SEQ files are always full-screen low resolution animations, so the sequence resulting from expanding all the data will be n 320 by 200 pixel low resolution screens, where n is given in the .SEQ header.

Since only the changes from frame to frame are stored, image data for a frame will rarely be 320x200 (except for the very first frame, which will always be a full screen). Instead what is stored is the smallest rectangular region on the screen that contains all the changes from the previous frame to the current frame. The x offset and y offset in the frame header determine where the upper left corner of the "change box" lies, and the width and height specify the box's size.

Additionally, each "change box" is stored in one of five ways. For each of these, the screen is assumed to have the full-screen image from the last frame on it.

o uncompressed copy: The data for this frame is uncompressed image data, and is simply copied onto the screen at position (x, y) specified in the frame header.

o uncompressed eor: The data for this frame is exclusive or'ed with the screen at position (x, y).

o compressed copy: The data for this frame must be decompressed (see below), and then copied onto the screen at position (x, y) specified in the frame header.

o compressed eor: The data for this frame must be decompressed (see below), and then exclusive or'ed with the screen RAM at position (x, y).

o null frame: The width and/or height of this frame is 0, so this frame is the same as the previous frame.

Of the 5 methods above, the one that results in the smallest amount of data being stored for a particular is used for that frame.

Compression Scheme:

Compression is similar to that employed by Tiny, but is not quite as space-efficient.

Control word meanings:

For a given control word, x:

x < 0 Absolute value specifies the number of unique words to
take from the data section (from 1 to 32767).
x > 0 Specifies the number of times to repeat the next word
taken from the data section (from 1 to 32767).

Note that a control word of 0 is possible but meaningless.

Format of expanded data:

The expanded data is not simply screen memory bitmap data; instead the four
bitplanes are separated, and the data within each bitplane is presented
vertically instead of horizontally. (This results in better compression.)

To clarify, data for a full screen would appear in the following order:

```
bitplane 0, word 0, scanline 0
bitplane 0, word 0, scanline 1
...
bitplane 0, word 0, scanline 199
bitplane 0, word 1, scanline 0
bitplane 0, word 1, scanline 1
...
bitplane 0, word 1, scanline 199
...
bitplane 0, word 79, scanline 199
bitplane 1, word 0, scanline 0
...
bitplane 3, word 79, scanline 199
```

Note however, that the data does not usually refer to an entire screen, but
rather to the smaller "change box," whose size is given in the frame header.

<Animatic Film> *.FLM (low resolution only)

```
1 word number of frames
16 words palette
1 word speed (0 - 99; value is 99 - # vblanks to delay between frames)
1 word direction (0 = forwards, 1 = backwards)
1 word end action (what to do after the last frame)
0 = pause, then repeat from beginning
1 = immediately repeat from beginning
2 = reverse (change direction)
1 word width of film in pixels
1 word height of film in pixels
1 word Animatic version number (major) [< 2]
1 word Animatic version number (minor)
1 long magic number 27182818 (hex)
3 longs reserved for expansion (should be all zeros)

32 words total for header
```

? words image data (words of screen memory) for each frame, in order

<Animaster Sprite Bank> *.ASB (low resolution only)

```
1 word number of frames - 1
1 word ?
1 byte maximum width, in pixels
1 byte maximum height, in pixels
16 words palette
--------
38 bytes total for header

For each frame {
1 word width of this frame (in pixels) - 1
1 word height of this frame (in pixels) - 1
1 word ?
? words image data (words of screen memory)
}

<STOS> *.MBK

9 words ?
1 long $19861987 (magic number?)
1 long offset from this long to header for low resolution
parameter block (if past end of file, no low res frames)
1 long offset from this long to header for med resolution
parameter block (if past end of file, no med res frames)
1 long offset from this long to header for high resolution
parameter block (if past end of file, no high res frames)
1 word number of low resolution frames
1 word number of medium resolution frames
1 word number of high resolution frames

For each frame {
1 long offset to data (probably only used internally by STOS)
1 byte width in words (multiply by 16 to get width in pixels)
1 byte height in pixels
1 byte X hotspot location
1 byte Y hotspot location
}

(The format implies other stuff could be here.)

1 long ["PALT" $50414C54]
16 words palette

? words of data for each frame, in the order mentioned in the
header. Monoplanar mask data follows image data for each frame.
----------
? words total

The frames often seem to be in semi-random order, not necessarily in
the order they are to be animated.

<GEM Bit Image> *.IMG

1 word version number of image file [1]
1 word length of header in words [usually 8]
```

1 word number of color planes [1 for monochrome]
1 word pattern length in bytes [1-8, usually 2 for screen images]
1 word pixel width in microns (1/1000 mm, 25400 microns per inch)
1 word pixel height in microns
1 word line width in pixels
1 word number of lines

? words header length defined in 2nd word of header

? bytes data

NOTES: If the image is a color image (planes > 1), the planes are stored separately starting with plane 0. There is, however, no standard way of storing the color palette. Some programs may save the palette in separate files, some may extend the header. For this reason, you should never assume the header is 8 words long, always get the header length from the 2nd word of the header. Also, the line width in the 7th word is the number of pixels in a line. Since the data is encoded in byte-wide packets, the actual unpacked line width is always a multiple of 8, and may be 1-7 pixels longer than the length specified in the header.

For each byte x in the data section,

x = 0 Pattern/scanline run.
Read the next byte, n (unsigned).

If n > 0 then:
Read a number of bytes equal to the "pattern length" word in the header. Repeat this pattern n times.

If n = 0 then:
Scanline run. Data for the next scanline is to be used multiple times. Read the following record:

1 byte flag byte [$FF]
1 byte number of times to use next scanline data

The data for the next scanline follows, compressed normally.

x = 80 (hex) Uncompressed bit string. The next byte determines the number of bytes to use literally. The literal data bytes follow.

otherwise Solid run. The value of x determines what to draw. The high bit specifies whether the pixels are set or cleared. A 1 indicates a byte-run using $FF, a 0 indicates a byte-run using $00. The low 7 bits, taken as an unsigned quantity, specify the length of the run in bytes.

<STAD> *.PAC (high resolution only)

4 bytes "pM86" (vertically packed) or "pM85" (horizontally packed)
1 byte id byte
1 byte pack byte (most frequently occuring byte in bitmap)
1 byte "special" byte
----
7 bytes total for header

? bytes data

The data is encoded as follows. For each byte x in the data section:

x = id byte Read one more byte, n. Use pack byte
n + 1 times.
x = "special" byte Read two more bytes, d, and n (in order).
Use byte d n times.
otherwise Use byte x literally.

<Imagic Film/Picture> *.IC1 (low resolution)
*.IC2 (medium resolution)
*.IC3 (high resolution)

4 bytes "IMDC"
1 word resolution (0 = low res, 1 = medium res, 2 = high res)
16 words palette
1 word date (GEMDOS format)
1 word time (GEMDOS format)
8 bytes name of base picture file (for delta compression), or zeroes
1 word length of data (?)
1 long registration number
8 bytes reserved
1 byte compressed? (0 = no, 1 = yes)

If compressed {
1 byte delta-compressed? (-1 = no, > -1 = yes)
1 byte ?
1 byte escape byte
}
----
65 bytes total for header (68 bytes if compressed)

? bytes data

Compressed data may be either stand-alone or delta-compressed (relative
to the base picture named in the header). Delta compression involves
storing only how the picture differs from the base picture (i.e., only
portions of the screen that have changed are stored). This is used to
to encode animated sequences efficiently.

Compressed data, stand-alone:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).

```
If n >= 2, use the next byte n times.
If n = 1, keep reading bytes until a
byte k not equal to 1 is encountered.
Then read the next byte d.
If the number of 1 bytes encountered is o,
use d (256 * o + k) times. I.e.,

if (n == 1) {
o = 0;
while (n == 1) {
o++;
n = next byte;
}

k = n;
d = next byte;

Use d (256 * o + k) times.
}
else {
d = next byte;
Use d (n) times.
}

x != escape byte Use x literally.

Compressed data, delta compressed:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).

If n >= 3, use the next byte n times.
If n = 1, do the same as for n = 1 in
stand-alone compression (above).
If n = 2, then set n = next byte.
If n = 0, end of picture.
If n >= 2, take n bytes from base
picture.
If n = 1, do the same as for n = 1
in stand-alone compression (above),
but take (256 * o + k) bytes from
base picture.

x != escape byte Use x literally.

<IFF Format> *.IFF

4 bytes "FORM" (FORM chunk ID)
1 long length of file that follows
4 bytes "ILBM" (InterLeaved BitMap file ID)

4 bytes "BMHD" (BitMap HeaDer chunk ID)
1 long length of chunk [20]
20 bytes 1 word = image width in pixels
```

```
1 word = image height in lines
1 word = image x-offset [usually 0]
1 word = image y-offset [usually 0]
1 byte = # bitplanes
1 byte = mask (0=no, 1=impl., 2=transparent, 3=lasso)
1 byte = compressed [1] or uncompressed [0]
1 byte = unused [0]
1 word = transparent color (for mask=2)
1 byte = x-aspect [5=640x200, 10=320x200/640x400, 20=320x400]
1 byte = y-aspect [11]
1 word = page width (usually the same as image width)
1 word = page height (usually the same as image height)

4 bytes "CMAP" (ColorMAP chunk ID)
1 long length of chunk [3*n where n is the # colors]
3n bytes 3 bytes per RGB color. Each color value is a byte
and the actual color value is left-justified in the
byte such that the most significant bit of the value
is the MSB of the byte. (ie. a color value of 15 ($0F)
is stored as $F0) The bytes are stored in R,G,B order.

4 bytes "CRNG" (Color RaNGe chunk ID)
1 long length of chunk [8]
8 bytes 1 word = reserved [0]
1 word = animation speed (16384 = 60 steps per second)
1 word = active [1] or inactive [0]
1 byte = left/lower color animation limit
1 byte = right/upper color animation limit

4 bytes "CAMG" (Commodore AMiGa viewport mode chunk ID)
1 long length of chunk [4]
1 long viewport mode bits (bit 11 = HAM, bit 3 = interlaced)

4 bytes "BODY" (BODY chunk ID)
1 long length of chunk [# bytes of image data that follow]
? bytes actual image data

NOTES: Some of these chunks may not be present in every IFF file, and may
not be in this order. You should always look for the ID bytes to find a
certain chunk. All chunk IDs are followed by a long value that tells the
size of the chunk (note that "ILBM" is not a chunk ID). This is the number of
bytes that FOLLOW the 4 ID bytes and size longword. The exception to this is
the FORM chunk. The size longword that follows the FORM ID is the size of the
remainder of the file. The FORM chunk must always be the first chunk in an
IFF file.

The R,G,B ranges of AMIGA and ST are different (AMIGA 0...15, ST 0...7),
as is the maximum number of bitplanes (AMIGA: 5, ST: 4).

Format of body data

An expanded picture is simply a bitmap. The packing method is PackBits
(see below), and is identical to MacPaint and DEGAS Elite compressed.
```

The (decompressed) body data appears in the following order:

```
line 1 plane 0 ... line 1 plane 1 ... ... line 1 plane m
[line 1 mask (if appropriate)]
line 2 plane 0 ... line 2 plane 1 ... ... line 2 plane m
[line 2 mask (if appropriate)]
...
line x plane 0 ... line x plane 1 ... ... line x plane m
[line x mask (if appropriate)]
```

The FORM chunk identifies the type of data:

```
"ILBM" = interleaved bit map
"8SVX" = 8-bit sample voice
"SMUS" = simple music score
"FTXT" = formatted text (Amiga)
```

<MacPaint> *.MAC

```
1 long version number [0=ignore header, 2=header valid]
38 * 8 bytes 8x8 brush/fill patterns. Each byte is a pattern row,
and the bytes map the pattern rows top to bottom. The
patterns are stored in the order they appear at the bottom
of the MacPaint screen top to bottom, left to right.
204 bytes unused
-------------
512 bytes total for header

< 51200 bytes compressed bitmap data
-------------
< 51712 bytes total
```

NOTE: The version number is actually a flag to MacPaint to indicate if the brush/fill patterns are present in the file. If the version is 0, the default patterns are used. Therefore you can simply save a MacPaint file by writing a blank header (512 $00 bytes), followed by the packed image data.

Bitmap compression:

The bitmap data is for a 576 pixel by 720 pixel monochrome image. The packing method is PackBits (see below). There are 72 bytes per scan line. Each bit represents one pixel; 0 = white, 1 = black.

<RGB Intermediate Format> *.RGB (low resolution only)

This format was invented by Lars Michael to facilitate conversions between standard ST picture formats and higher resolution formats like GIF and IFF. It supports 12 bits of color resolution by keeping the red, green and blue components in separate bit planes.

```
1 word resolution (ignored)
16 word palette (ignored)
16000 words red plane (screen memory)
1 word resolution (ignored)
```

16 word palette (ignored)
16000 words green plane (screen memory)
1 word resolution (ignored)
16 word palette (ignored)
16000 words blue plane (screen memory)

96102 bytes total

The format was derived by concatenating three DEGAS .PI1 files together --
one for each color gun. The RGB value for a pixel is constructed by looking
at the appropriate pixel in the red plane, green plane, and blue plane. The
bitplanes are in standard ST low resolution screen RAM format, but where pixel
values in screen RAM refer to palette entries (0 through 15), pixel values
here correspond to absolute R, G, and B values. The red, green, and blue
components for each pixel range from 0 to 15 (4 bits), yielding a total of
12 bits of color information per pixel. Not coincidentally, this is exactly
the format of ST palette entries (although on ST's without the extended
palette only the lower 3 bits of each color component are used).

You can view a single bit plane on a standard ST by splitting the .RGB file
into its three DEGAS .PI1 components and setting the palette to successively
brighter shades of gray.

<ComputerEyes Raw Data Format> *.CE1 (low resolution)
*.CE2 (medium resolution)

1 long [$45594553 or "EYES"]
1 word resolution [0 = low res, 1 = medium res]
8 words ?
If resolution = 0 {
64000 bytes red plane, 320 x 200, 1 pixel per byte
64000 bytes green plane, 320 x 200, 1 pixel per byte
64000 bytes blue plane, 320 x 200, 1 pixel per byte

192022 bytes total
}
else If resolution = 1 {
128000 words 640 x 200, 1 pixel per word

256022 bytes total
}

This is almost two formats in one:

Low resolution:

The planes are arranged vertically, instead of horizontally.
The first byte is the red component of pixel (0,0), the second is (0,1),
and the third (0,2). The 201st corresponds to (1,0), etc. The 64001st
byte is the green component of (0,0).
Only the low six bits of each byte are used.

Medium resolution:

The picture is arranged vertically, instead of horizontally.
The first word is pixel (0,0), the second is (0,1), and the third
(0,2). The 200th is (1,0) etc.
Each word is divided up into the RGB values for the corresponding
pixel, as follows:

```
Bit: (MSB) 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00 (LSB)
-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --
0 B4 B3 B2 B1 B0 G4 G3 G2 G1 G0 R4 R3 R2 R1 R0
```

Bit 15 is not used.

<PackBits Compression Algorithm>

The following packing algorithm originated on the Mac, was adopted by
Electronic Arts/Commodore for use in the IFF standard, and then by Tom
Hudson for use in DEGAS Elite. The algorithm is currently used in
MacPaint, IFF, and DEGAS Elite compressed file formats. Each scan line
is packed separately, and packing never extends beyond a scan line.

For a given control byte 'n':
0 <= n <= 127 : use the next n + 1 bytes literally (no repetition).
-127 <= n <= -1 : use the next byte -n + 1 times.
n = -128 : no operation, not used.

---

* Roland Waldi contributed extensive information on the following formats:

GEM, IMG, Doodle, STAD, Imagic Film/Picture, Art Director, IFF

** John Brochu, ST picture formats guru, provided sage advice and many
corrections to the following formats:

NeoChrome, DEGAS Elite Compressed, Spectrum 512 Compressed,
GEM Bit Image, IFF, MacPaint

Compliments? "Thank you for saving power by not turning your printer on." :)

Actually, a say() function would be a good idea if the voice would be of better quality than is usual. I remember a program called STSPEECH.TOS that would say whatever you typed (and could be made to stay resident and be tweaked by other programs to say what THEY want it to say) but the voice it spoke with was awful. It was the voice commonly associated with computers. Grating.

Is it possible to get better quality phonetics, or at least generate more human-sounding sounds?

3670. Re: No red in monitor

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 06:05:27 UTC
From: jad2433@ritvax.isc.rit.edu
Message-ID: <1992Sep30.060527.20549@ultb.isc.rit.edu>
Source record: 42683

In article <BvAs2G.2up@acsu.buffalo.edu>, v5914ane@ubvmsd.cc.buffalo.edu (Steve) writes:
>Does anyone have any Idea on why my atari color monitor lost the red in the
>picture??

In this case there are some immediate things to check.

Making sure its unpluged and discharged of any static electricity, open the monitor casing removing the back cover housing.

You need to use an Ohm meter or something that can show continuity (a good connection). The end that plugs in to the computer has several pins in it. The Atari Pin out diagram in the ST manual will come in handy here.

This is what the computer in put has, so the Color monitor will only have some of these connected.

1 - Audio out (from computer into monitor)
2 - Composit Video (usually not connected)
3 - General Purpose Output (usually not connected)
4 - Monichrome detect (not on color cable)
5 - Audio in (into computer out of monitor not connected)
6 - Green Yes, this should definately be connected
7 - Red Probably your broken wire----------<<<<<<<!
8 - Plus 12-Volt Pullup
9 - Horizontal Sync
10 - Blue Yes definately should be there
11 - Monichrome (not connected on color monitor)
12 - Vertical Sync
13 - ground

Use the continuity checker to see if you have a good cable. The one end will obviously be the end with all the pins that usually connects to the back of the computer, and the other will connect to some weak pins on the PC board of the Monitor, so be carefull if you remove this from the monitor.

When I had this problem My cable was good, but the pin that the cable connected to in the monitor was broken. With a little Solder and a bit of patience it was back and running in no time.

If the cable is good and the connections to the PC board are good inside the monitor, now things get a little rough.

Either the Red Gun on the monitor has failed, or something in the monitor controling the red gun has failed, or the problem is in the ST.

If you know someone with a working monitor, or another ST, the location of the problem can be determined by swapping things arround and seeing what works or

does not work.

If the ST is determined to have the problem, start with the Plug, and from there you are on your own. I hope its just the peskey cable or one of the pins on the minitors PC board. Good luck.

If you need any other help Mail my account JAD2433@rit.edu

3671. XBTIMER

Date: 1992-09-30 06:06:55 UTC
From: mike@r-node.gts.org
Message-ID: <1992Sep30.060655.1846@r-node.gts.org>
Source record: 42688

Hello all.

Sorry if this is an old topic, but would appreciate any help:

If I want to use the xbtimer call:

1) How do the combination of the 'divider' and 'data' values
work when calculating how often the interrupt will occur?

2) If the timer A data, is the 'count down'
value, is there any way of checking the MFP registers to
find out what the original 'count down' value that was
loaded?

3) How do I terminate/return in my timer interrupt routine
RTS, RTE ... do I need to reset any regs in the MFP?

4) Is there a time limit on the execution of my interrupt
routine?

Thanks for any suggestions.

Mike

3673. Re: Revised Picture Formats List (was Re: Cyber Seq. Info and Question)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 08:44:41 UTC
From: neil@cs.hw.ac.uk
Message-ID: <1992Sep30.084441.2439@cs.hw.ac.uk>
Source record: 42675

Thanks for the latest edition Dave.

Now listen people. If you look at Dave's list you will see that it bears a copyright message. The reason for this is that about 2 years ago ST Format quoted Dave's list and gave no-one (neither Dave or any of the contributors) the credit for any of it. This years September issue of Atari ST User did the same despite the copyright and note on distribution. I wrote to them and recieved no reply. These magazines are slime!

Dave and many of us have put lots of work into reverse engineering and documenting these file formats and these magazines are quite happy to pillage the work without due credit. Dave doesn't ask for money or try to restrict the distribution of the knowledge of these formats. All he asks is that the many contributors be respected and given credit where credit is due.

Since the picture formats list was taken from this group by these magazines I'm sure they will read this too:-

Dirty Slimy Magazine List

ST Format (a.k.a ST Doormat)
Atari ST User (a.k.a ST Luser)

>
>I've got a 6-chip set of TOS 1.4 and need to know which chips go into which
>sockets. I had this information before but it's long gone now.

Edited from a rare (by Atari UK standards :-) technical note (ST/HW/0060):-

TOS 1.4

ST STFM Mega Cksm Part No. Rom

U2 U48 U3 2097 C300641-001 HI-2
U3 U59 U6 2AAA C300642-001 HI-1
U4 U63 U9 F6F2 C300643-001 HI-0
U5 U53 U4 9FC5 C300644-001 LO-2
U6 U62 U7 305D C300645-001 LO-1
U7 U67 U10 64BB C300646-001 LO-0

In a Mega you must also change jumpers W2 and W3 so that they both link
positions 1 and 2. Install a jumper in location W4 and finally remove chip
U12 (74lS11).

(With appropriate hand gestures to Luser and Doormat who may want to reproduce
this information :-)

3675. help needed on GEM programming

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 09:35:26 UTC
From: grellier@ufrima.imag.fr
Message-ID: <BvDxB3.77G@ufrima.imag.fr>
Source record: 42677

I've got trouble with the WM_REDRAW message which is easily
smashed by other messages like WM_M1. How avoid it ?
More exactely, my problem happens when the user calls the
information dialog box on the menu whereas the program is
also waiting for a WM_M1 message. When he clicks on Ok, the
button is in the area and so the redraw message of the end of
the dialog is smashed by the MU_ENTRY event.

Thanks for answering to me.

Thierry grellier

PS: I program in C.

3676. reading vblank counter on TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 10:35:59 UTC
From: klassa@aurs01.UUCP
Message-ID: <61227@aurs01.UUCP>
Source record: 42679

Hi-

Somebody recently sent me some code that uses Superexec() to call a routine
that reads the system vblank counter... The message was (in edited form):

```
> Ok. Try something like this:
>
> Supexec( get_vbl_count ); /* Supexec() is an XBIOS function that */
> /* executes a subroutine in supervisor */
> /* mode. */
> get_vbl_count()
> {
> /*
> system variable at address 0x466 - the number of vertical blank interrupts
> */
> unsigned long count = *((unsigned long *)0x466);
> return( count );
> }
```

This works perfectly on an ST, but doesn't seem to work on a TT. I
would think that the counter is in the same place in system memory on
both machines...

Can anybody tell me why this doesn't work on a TT, and what I can do
to make it work?

Thanks!!

John

>Huh? I've been working/programming with my ST for several years now, and
>have never encountered those 'severe bugs' you're talking about. Could you
>tell use more about them, please? Esp. when they show up, of course :).

Try to change the size of a window and make a double click into another
window or into the menu bar. Or try to drag an icon into the menu bar an
make a fast double click. Or only try to type with ten fingers in Wordplus.
Experienced secretaries and fast typers freeze a TOS two times a day.

>And the original poster had obviously forgotten to
>do an appl_init() call and a>v_opnvwk() call, as someone else noted in a
>previous posting, so probably>*that* was the problem, and not those 'severe
>bugs'.

Of course, you should do appl_init(), but in TOS 1.04 it is a dummy
function (not in multitasking systems!). appl_exit() is very important!
You don't need v_opnvwk(), when you don't need VDI calls. Why open a door
without entering?

>AES/VDI could all have been better, but they're not *that*
>bad.

They are, try to write stable and fast programs in standard TOS and VDI!

From: ddv@unix.brighton.ac.uk
Message-ID: <1992Sep30.131652.26664@unix.brighton.ac.uk>
Source record: 42553

there are bios routines to check to see if the io/kbd ports have pending data,
for the first problem.
the second is the standard function (stdio) that gets a char from a stream
that may have been 'pushed back' onto it.
This should be defined as

```
getch()
{
return ((bufp>0) ? buf[--bufp] : getchar() );
}
```

ie get the char from the buffer if the next one is there, otherwise
read one via buffer'd io routine getchar() (that will fill the buffer).

3679. Fontgdos

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 13:33:45 UTC
From: jtreichl@iiic.ethz.ch
Message-ID: <1992Sep30.133345.2280@neptune.inf.ethz.ch>
Source record: 42678

I have a problem with the fontgdos. probably i missed the discussion about
the it.

1. i installed the cpx modules and generated the assign.sys and
the extend.sys file. they seem to be correct.

2. put fontgdos.prg in the auto folder an boot.

3. i wrote a little test programm with a vst_load_font call for
the screen device.
GDos error: not enough cache memory.
but i have set the cache sizes on 20,20,200 and no font is bigger
than 60kByte.

what's wrong.

regards
Juerg

3680. MIDI programs

From: ZZDLG@LIVERPOOL.AC.UK
Message-ID: <92274.151059ZZDLG@LIVERPOOL.AC.UK>
Source record: 42682

Hi Folks,
I am having great fun producing a Patch Librarian for my Yamaha HE8.
The big problem is that the HE8 sends lots of "Active sense" messages
which quickly flood the 128 byte buffer. I have fo course tried a bigger
buffer but it dosn't seem to make much difference. I suppose the only
solution is a interupt handler which discards the "sense" messages.
I know other have run into this problem, so can any one else lend me
some code, or otherwise help. Dave.
p.s. replies by EMAIL would be much appreciated as I don't always
get chance ot read this list.

From: castermn@tokyo.seri.philips.nl
Message-ID: <1992Sep30.152216.5820@phcomgw.seri.philips.nl>
Source record: 42684

Hello world,

Is there somebody out there who has experience
in handling exceptions for a 6888x ?

I am building Yet Another Function Plotter. Upon
excecution of the formula an alert should be displayed
whenever "operand overflow", "illegal argument" etc
occurs.

I used Pure C which supports 6888x but the 'signal()' function
does not handle 6888x exceptions.

I asked Eric Smith but MiNT currently does not support
6888x exceptions. It supports 6888x on context switch.

Is GNU as solution ?

I tried to write a handler in assembler, this failed up to
now because of insufficient TOS/assembler knowhow. And because
I cannot debug these things. During exception handling the
Trace-bit is OFF so the debugger does not stop.

Who knows a solution ? Assembly / C source / ideas welcome

Thanks,

3684. Boot sector

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 15:50:21 UTC
From: max@kernighan.cba.csuohio.edu
Message-ID: <1992Sep30.155021.6388@news.csuohio.edu>
Source record: 42686

In reference to bytes 8 to 10 on the boot sector (using numbering scheme from 0 to 511), which is the 24-bit serial number of the disk:

1. Is it necessary for this number to be unique or non-zero?

2. Will anything change if this number is zero from disk to disk?

3. What was the intended purpose of this number?

I have been attempting to write as many binary zeros to the boot sector as possible without changing operation of the disk, and seem to have success in making the boot sector ALL binary zeros except for this minimal required information (using numbering scheme from 0 to 511):

A. For a non-executable boot sector:

1. Bytes 0-10 can be zero (see questions above about serial number).

2. Bytes 11-29 need meaningful values describing the disk.

3. Bytes 30-509 can be zero.

4. Bytes 510-511 need to be any 16-bit value OTHER THAN the checksum of bytes 0-509. In all cases except for one case out of 65536, this number can be zero also.

When you are making a non-executable boot sector, use xbios 0x18, which calculates the checksum of the boot sector and adds one to it (I believe) to mess up the checksum so that it is not signaled as being executable.

B. For an executable boot sector:

1. Bytes 11-29 need meaningful values describing the disk.

2. Bytes 510-511 need to be the 16-bit checksum of bytes 0-509, signaling that the boot sector is executable. Xbios 0x18 can calculate this for you.

3. Everything else is your boot program. TOS branches to the first byte of the boot sector wherever in memory it has been loaded.

When you are making an executable boot sector, use xbios 0x18, which calculates the checksum of the boot sector and places it in bytes 510-511 to signal it as being executable.

Typically, bytes 0-1 are a PC-relative branch forward to byte 30
of the boot sector, where the 16-bit value in memory location 0x482
is set to one and a return from subroutine ends the boot program
(actually subroutine), at which point TOS runs "COMMAND.PRG".

However, I don't believe that bytes 0-1 absolutely must be a branch
instruction. I believe bytes 0-10 and 30-509 can be any value you
want (even though 8-10 is the serial number), and can therefore be
used for your program (why not make the serial number part of a
program?!). You just have to remember to skip over the disk
description section of bytes 11-29 before you start executing it,
so you would typically use the branch right at bytes 0-1.

Anyone with information about the serial number questions as asked above
or corrections to the rest of this information, please post a follow-up.

3685. Re: reading vblank counter on TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 17:11:40 UTC
From: klassa@aurs01.UUCP
Message-ID: <61234@aurs01.UUCP>
Source record: 42541

In article <61227@aurs01.UUCP> I write:

>Somebody recently sent me some code that uses Superexec() to call a routine
>that reads the system vblank counter... The message was (in edited form):
>
>> Supexec(get_vbl_count); /* Supexec() is an XBIOS function that */
>> /* executes a subroutine in supervisor */
>> /* mode. */
>> get_vbl_count()
>> {
>> /*
>> system variable at address 0x466 - the number of vertical blank interrupts
>> */
>> unsigned long count = *((unsigned long *)0x466);
>> return(count);
>> }
>
>This works perfectly on an ST, but doesn't seem to work on a TT. I
>would think that the counter is in the same place in system memory on
>both machines...
>
>Can anybody tell me why this doesn't work on a TT, and what I can do
>to make it work?

I've since discovered that it does work on a TT, but not in the
context in which I *WANT* it to work. :-(

A simple test program that calls Supexec(get_vbl_count) 100 times and
prints the result returns reasonable numbers on a TT... I get between
9 and 12 of each number, and the numbers increase by one with each
change (i.e. like 610, 610, 610, ... < 6 or 8 more of 'em > ... 613,
613, ... and so on).

However, when I put similar code into a game I'm writing, it flops.
It could be that *I've* hosed it up (I'm certainly not beyond making
mistakes), but it only fails on a TT. The way I've got it set up is
as follows...

In main(), I set old_vblanks to Supexec(get_vbl_count). Then, with
each iteration of the main loop, I check to see whether I've taken
more time than I wanted to, to complete that iteration. If so, I
display a message that says, in essence, "you've taken too long..."
If not, I do a Setscreen() to flip pages (i.e. I double-buffer), then
a Vsync() to wait for the next vblank. Then, lastly, I set
old_vblanks to Supexec(get_vbl_count) again, and loop around to do the
next iteration.

Like I said, on an ST, it works just like it's supposed to. On a TT,
I get the "you've taken too much time" message immediately. If
anything, I should see that message MUCH less often on a TT, since it
ought to be able to whip through things MUCH faster than an ST does
(no TT flames, please... :-)).

HELP!

Thanks!
John

3686. Re: reading vblank counter on TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-09-30 17:15:42 UTC
From: klassa@aurs01.UUCP
Message-ID: <61235@aurs01.UUCP>
Source record: 42546

I goofed... In my sample results, I should have written:

>A simple test program that calls Supexec(get_vbl_count) 100 times and
>prints the result returns reasonable numbers on a TT... I get between
>9 and 12 of each number, and the numbers increase by one with each
>change (i.e. like 610, 610, 610, ... < 6 or 8 more of 'em > ... 611,
>611, ... and so on). ^^^
^^^

The original message read "610, ..., <stuff>, ..., 613, 613, ..." and
^^^ ^^^
was incorrect. The sequence definitely increases by one each time a
change occurs.

Thanks...
John

>1. Is it necessary for this number to be unique or non-zero?
It must be unique.

>2. Will anything change if this number is zero from disk to disk?
No. Thats the problem, the OS (Operating System) will not change the disk data in it's buffers when you change the disk in the drive. See below for more details.

>3. What was the intended purpose of this number?
So the OS can tell if the disk was changed or not since the last vertical blank interupt.

If you remove a disk from the drive and put in another disk with the same serial number, the OS will not be able to tell that the disk was changed. This is a problem since the OS buffers up things like the FAT and does not flush/reload these buffers unless it thinks the disk was changed. If you then try to write to the new disk the disk will become corrupt because the OS is using info from another disk about where files/data should go.

Note that passing a 0 for a serial # to Flopfmt() will cause Flopfmt() to create a random number to use as the serial #. If you don't pass a 0 you should pass a random number.

Yes, it's possible, I was at a store that had both STs and Amigas,
and they had a 500 actually attached to SC1224. Now I have no idea what
the pinouts are, but it is possible.

From: terjeve@ifi.uio.no
Message-ID: <TERJEVE.92Sep30215219@kolsaas.ifi.uio.no>
Source record: 42690

Where can I find source for gcc2.2.2 for the ST? It must recognize
the -mbaserel and -mpcrel options (as the gcc in gc222bin.zoo at a.a
does).

Diffs to the original gcc.2.2.2-distribution would be fine.

>wrong, please let me know also. :-)

>Joel Banks
>dumgrunt@ccwf.cc.utexas.edu

OOHH ! MUCH TOO COMPLICATED !
Here is a simpler solution:
Use a set of 64KB Eproms (27512) instead of the original 32 KB Roms.
Now burn in each chip in address space $0000-$7fff Tos Version 1 and
in address space $8000-$ffff Tos Version 2 .
(of course you have to use always rom-files with the same name, e.g.
U2 (or HI-2) of TOS 1.0 and U2 of Tos 1.4 must be stored in your first eprom)

Then you can put the 6 eproms in your sockets (they are pin-compatible) and
use pin #1 (A15) of each eprom, to switch between your two tos-versions.
On newer boards you find pin #1 of all rom-sockets at a jumper called 'A16'
Otherwise you have a bit of extra work to do ....

Any questions ??

ciao
Gunter

It would be a bit expensive: your controller is of no use.
You should get a host-adapter (from ICD or any other) to
change your DMA output (ACSI protocol) to an SCSI and
then a controller (OMTI or ADAPTEC or something) to
change from SCSI to MFM (or RLL). And you would need
some power supply, a case, etc...,
The only thing you could use is that 20B HD, which is likely
to be slow (and not worth much more than 50-100$)

For the drivers: no problems, it's standard.

All in all, just get a new HD, plain SCSI: it's gonna be faster,
cheaper, better...

Stefan

```
[ concerning the serial number on the bootsector ]

As far as I know, the serial number is used to signal a disk swap.
If two disks have the same serial, the OS can't know you've changed disks.

[concerning the XBIOS 0x18 ]

I suppose you mean XBIOS 18 / XBIOS 0x12 ? XBIOS 0x18 (0x18 = 24) is
'Bioskeys'...

You need to chuck the AT WD controller and swap it for an Adaptec 4000 MFM controller. I assume the drive is MFM, because I don't know of any 20M RLL drives. If, indeed it is RLL, you'll need to use an Adaptec 4070 instead. Once connected to the 4000, you just hook the SCSI connector onto your Host Adaptor (from ICD, Supra, BMD, etc.).

I currently use two IBM-style drives on my machine through an Adaptec 4070. By the way, these IBM drives are usually referred to as ST506/412 drives, I believe, based on the original Seagate 5M drive of the same name (ST506).

Good luck!

Regarding the boot sector serial number, bytes 8-10 using a scheme of numbering from 0-511:

I don't believe that the serial number is meaningful. From my tests of simply zeroing the serial number on a couple of disks and displaying, deleting, and copying files and subdirectories, all the while changing from one disk to the other (with the same serial number), I definitely COULD NOT obtain any errors.

From what I can tell, the serial number on the Atari ST's boot sector need not be unique, and can be the same from disk to disk. Furthermore, the boot sector appears to be reread each time you pop out a disk and place a new one in. The default directory changes to the root directory if the disk has been changed (except for the GEM desktop, which tries to descend to the current directory as displayed in the title bar).

Perhaps the BIOS #9 call (disk was, was not, or may be changed) is used to see if the disk was changed prior to all disk operations. If it was or may have been changed, the boot sector would be reread and default to the root directory (the reasonable thing to do).

Well, you don't have to believe us... they're your disks..

You might want to call Dave Small and ask him how significant
the serial number on floppy disks is first though.

When ANTIC magazine first released his formatting program,
"Twister", someone at the magazine inadvertantly changed
something in the source code, and the program generated the same
serial number on every disk.

It wasn't until AFTER all the complaints came in that they caught
it, but not in time to prevent a lot of disks from being trashed,
or for Twister getting a bad reputation (undeservedly so, too..).

The revised version has the random serial number in it, and works
just fine...

Source record: 42558

Someone wrote me and suggested that I explain my situation a little more... Here's an edited version of my response to them.

The topic is: "Why does a method of timing that uses the system vblank counter work on an ST but, seemingly, fail on a TT?"

The scenario: I'm writing a LodeRunner-type game. The game is set up so that it can handle a variable number of adversary "sprites." I wanted to be sure that all of my processing was getting done in under 3 or 4 vblanks (I don't remember which), so I put in some code to check things & let me know if I ever ran over the amount of time I wanted to stay under. If so, I figured I'd just reduce the number of adversaries until I got to a point where I never saw the "you're out of time" message.

The game stores the vblank count, does some processing, then compares the current vblank count with the one it stored away. If the difference is greater than some threshhold (like 3 or 4), the game displays a message to the effect that it couldn't process everything it needed to within the amount of time (3 or 4 vblanks) allotted to it.

Specifics...

I've got the following #define's:

```
#define VBLANKS Supexec(get_vbl_count) /* as per my first message on */
/* this topic */

#define TO_FRONT(x) { Setscreen(screen_buf[!x], screen_buf[x], -1); Vsync(); }

#define TIMING 3 /* the number of vblanks per update, minus 1 */
```

I've got an unsigned long variable I call old_vblanks.

I've got a function called restore_screen() which Setscreen()'s physbase and logbase back to what they were when the game started.

In main(), I've got something kind of like:

```
main()
{
init_everything();

old_vblanks = VBLANKS; /* store the old count away... */

while (!kbhit()) {
iterate();
}
```

```
}
```

In the iterate() code, I've got:

```
iterate()
{

/* stuff to restore the background */
/* stuff to save the background away for this iteration */
/* stuff to update positions */
/* stuff to determine new positions for everything */
/* stuff to draw everything at new positions */

/* and then (and this is right out of my code): */

if (VBLANKS - old_vblanks > TIMING) {
restore_screen();
printf("\nvblank timing not sufficient...");
while (!kbhit()) {}
getch();
}

while (VBLANKS - old_vblanks < TIMING) {}

TO_FRONT(pulse); /* pulse keeps track of whether I'm
writing to screen 0 or screen 1;
Warwick used this name in a
msg to me & I liked it so much
I kept it... :-) */

old_vblanks = VBLANKS;

pulse = !pulse;

return;
}
```

What happens, you ask? On a vintage, 8 MHz 1040 ST, I can run the thing with 7 adversaries & never see the "timing not sufficient" message. On a TT, I get the message immediately, and continually, until I exit the game.

One possibility is that, for some odd reason, the kbhit() call in main()'s while loop (which occurs once before the first call to iterate()) takes extremely long to complete on a TT... And because it does, the

```
(VBLANKS - old_vblanks > TIMING)
```

check in iterate() causes the "timing not sufficient" message to appear.

Another possibility is that my restore / save / update / redraw code (in iterate()) takes longer on a TT. I find this hard to believe, though... Especially since I ran the game with just one adversary (it's a LodeRunner-type game, in case you're wondering) on the TT & still got the message. With just one adversary, there's almost

nothing to do in the restore / save / update / redraw code. And like I said, I ran the *same* code on a vintage 1040ST, with 7 (SEVEN) adversaries -- MUCH, MUCH more to do in restore / save / update / redraw code -- and didn't see the message.

As a benchmark, an earlier version of the game didn't care about vblanks. It simply did what it did, then called Setscreen() / Vsync() whenever it was ready. It had the same kbhit() call in the while loop in main()... On that version, the TT would handle 7 adversaries in under one vblank (i.e. the game speed was the same with 7 adversaries as it was with just 1), and you wouldn't see a slowdown until you added the 8th one. On a vintage ST, you'd see a slowdown with just 2 adversaries. i.e. the TT flies through the kind of code this thing uses, so it *really* doesn't make sense that my vblank timer craps out in this latest version of my game...

Any clues? Is there anything a TT does worse than an ST, that I might have inadvertently used in this latest version of my game? Does it make a difference that I didn't compile the game on a TT? It wouldn't make any sense if it did make a difference, but at this point I'm just grasping at straws.

Any advice greatly appreciated...

Thanks!
John

BTW -- I'm using Heat & Serve C (Ian Lepore's version of Sozobon C), if that matters...

Well Bob the Write protect is used also for disk change, but some disk drives
(Chinnon) don't toggle it when the disk is write enabled, but the later Tos's
have some changes to the OS, to improve the disk change logic,
I do know that TOS 1.4 has and some of the later ones...

The version of the MiNT library that's currently available (patchlevel 20) does not work with Turbo C. However, Ulf Mueller and Michael Hohmuth have sent me patches, and the next version of the library will have Pure C and Turbo C support. I *hope* it will be available soon; I've been hoping that for several weeks now, and every time I think it's almost ready another bug appears :-(.

I have a simple to the historians out there which has mildly puzzled
me for some time.

Why was it decreed in the beginning that TOS should use FIVE
(512-byte) sectors to store its (12-bit) FAT Info.??

Surely no more that 3 of these sectors will EVER be needed (at
least for the 720 kbyte ATARI standard double sided format)!! Is this
not an example of ATARI wasting 2 whole sectors per FAT copy i.e. 2 kbytes
per Floppy?

Or am I missing something?

Subject: GEM events
Status: ORr

When you're testing GEM events, you may get more than one at a time.

{
event = evnt_multi(........);
if (event & MU_M1)
do_m1_stuff();
if (event & MU_KEYBD)
do_keybd_stuff();
.
.
.
}

NOT

{
event = evnt_multi(...........);
if (event & MU_M1)
do_m1_stuff();
else if (event & MU_KEYBD)
do_keybd_stuff();
.
.
.
}

Get rid of the else, and recieve multiple simultaneously returned events.

3706. floppy media change problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-01 14:43:51 UTC
From: svrobins@bra.isnet.inmos.co.uk
Message-ID: <1992Oct1.144351.25@bra.isnet.inmos.co.uk>
Source record: 42557

I have a TEAC 3.5" 720K floppy drive hooked up to my Mega 2 as drive B,
and have a problem with the ST not detecting when I've changed the disk
in the drive. I don't have the model number here, but I can get it if
its important.

The drive is connected with a Cumana cable/box which worked fine with
the original Cumana drive (the Cumana drive has since become my internal
drive).

The drive reads, writes, and formats disks ok, but when I change the
disk my ST usually shows the contents of the previous disk. On the desktop
this is'nt too much of a problem 'cos I can press ESCAPE to force the
disk info to be updated. If this happens within an application, when I
have the fileselector up its a real problem. On one memorable occasion
I trashed a disk this way, and lost a lot of work.

I vaguely remember some discussion on this thread a couple of years back.
Does anyone have any ideas on how to fix it ?

Thanks,

Paul Robins

One reason may be the MS-DOS-Disk compbattle. There one cluster is
mostly 1 Sector (720 kB disks), so they need more FAT-space (5 sectors).

You should not be worried about the 2 wasted kB, be happy and use 1
Sector Clusters (then you don't waste 1023 Bytes for a File with 1
Byte, you only wate 511 Bytes! So you win 512 Bytes by many Files!
Wow! It's only a little bit slower, but you are happy about every
Byte, right?)

The above is true from TOS 1.4 on!

Older TOS versions will not reread the FAT if the new floppy inserted
contains the same serial number. So be careful!

This was an ideal place to store code for a virus then, as
these 2 extra sectors were never used otherwise.

Quite big !!!
You can't change the clock from 8 Mhz to 25 Mhz and think that evrything will work fine !
First you need a new 68000 which runs on the new frequency (which is a bit more expensive then the standard 8 MHz)
And what is even worse: The rams in your ST (and the MMU) are not fast enough.
So you need a kind of automatic switch, which slows down your 68000 during read/write access to memory.
All in all it's quite a lot of work to do.... But there are many 'speeder' cards on the market, most of them with cache memory (runs at 16 Mhz).
So my sugestion: Get out and buy one of them (about $100-$200 I think)
It's too much work to develop it on your own !

Tos 1.x (x <= 2) is a problem. To get things going with tos 1.0
I had to guarantee that my new floppy drive toggled write protect when I removed/reinserted a non-write protected disk. Now tos 1.4 checks "serial numbers" and maybe other stuff too. But the floppy drive I used (ND352, I think that's Toshiba) only output valid write protect sensor info while it thought a disk was in the drive. So... I glued down the disk change sensor, so it would put out "valid" write protect info all the time. Worked like a charm.

Errm, the fastest 68000 cpu's have a standard clock ratio of 16MHz.
Besides, some accelerator boards are available which use selected
(and thus more expensive) 16MHz CPU's running at 25 MHz.

This is kinda crap, because the CPU will crash when overheated.

I would recommend a 68030 board anyway.

>Is it part of the GNU C package?

Well it is. Each anonymous-ftp site with gcc for the ST/TT-series
should contain gdb (at least at the atari-archive and here in Munich).
But gdb is in another dir! So look for the names of the directories.

Hope this helps,
Peter
pal@regent.e-technik.tu-muenchen.de

P.S Take the time to look into the other directories of the gnu-stuff.
There are lots of good and usefull tools in it, as well as needed
libraries.

3720. MiNT ** Can an application communicate with TOSWIN? **

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-03 00:18:31 UTC
From: mforget@ersys.edmonton.ab.ca
Message-ID: <kDL2RB1w165w@ersys.edmonton.ab.ca>
Source record: 42573
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have been thinking about writing a desktop replacement that takes advantage of MiNT. In order to do this, though, I would like to be able to tell TOSWIN to run a TOS/TTP program in the background (in a window).

Is there a way to do this? I know that I can start a process running in the background using the BG/LIMIT/NICE programs included in the MiNT utility package, but that method will not place the program being run in a Window like TOSWIN does.

The best possible situation would be if an application could tell TOSWIN to execute a program in a window, assign a priority to the program, and limit the ammount of memory it could use.

Is there a way to do anything remotely like this, short of writing my own program to handle the windows and control the output of each process?

Any help would be appreciated.

3724. Backing up the HD -- AGAIN

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-03 19:58:21 UTC
From: hack@stsci.edu
Message-ID: <1992Oct3.195821.19272@stsci.edu>
Source record: 42576
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

In my previous posting, I had requested some advice on the best utility to use in backing up my HD. My problems arise from not being able to find a program that will compress the files while backing them up or being able to restore the files once backed up.

In response, I was directed to use TURTLE. Unfortunately, this is the exact program I was referring to in my original post. After reading the docs to the version I know about (Version 3.20), it will NOT compress contrary to the advice, there is no method given for restoring said backed up files onto the HD again, and worst of all, I can not run it to back up onto DS 720k floppies because of shortage of memory for the RAMDISK.

If there is a newer version that overcomes these problems, please tell me/us about it. If there are simply undocumented options I do not know about, please tell me. Otherwise, any other suggestions will be greatly appreciated, even if it means purchasing the program.

Please accept my apologies in advance if I have offended anyone with my remarks about TURTLE. There just has to be something available that will do what I need, and it just wasn't it.

Date: 1992-10-03 21:21:21 UTC
From: johnmc@mks.com
Message-ID: <1992Oct3.212121.18545@mks.com>
Source record: 42578

Is there an easy way to *get* the current values for baud rate, parity, etc? I know how to set them with Rsconf(), but can't figure out how to retrieve the current values. One piece of code I saw (in the uupc.zoo file at atari.archive) suggested that Rsconf() returns this information encoded in a long, but no everything else suggests that Rsconf() is a void function.

I'd like to be able to save current values before changing them, and I'd like to be able to do it easily. Is there something blatantly obvious I'm missing? (Probably...)

Thanks for the help.

I've never seen one, but it would be a good project if people wanted to
contribute. I'd even volunteer to coordinate the compilation and editing of
the list. I have collected a few bug workarounds from various sources, and
I'm sure many people would find a canonical list helpful. Are there enough
that a seperate list would be needed for tos, aes and vdi?
If this project generates enough interest, I'd also like a few volunteers
to help test bugs, or help suggest the best work arounds.
Any interest?

Okay - there are only _2_ megs on the motherboard, and another _2_ on the daughterboard under the drive. Thus, you only have a _4_ meg machine. If it was sold to you as an 8M system, I think you have some questions to ask.

Don't bother trying to shift the board - it has 2 connectors on it, one at each end, and it will not fit. The DIP switches are mostly unused - DIP 8 controls whether or not the DMA sound hardware is advertised, and DIP 7 whether or not the OS thinks you have a HD drive.

> to run a TOS/TTP program in the background (in a window).

No problem -- TOSWIN opens up a pipe (u:\pipe\tosrun) and listens there for requests. To run a program in a TOSRUN window, you just have to write the initial directory for the program, program name, and arguments, all separated by spaces and terminated by a 0. (Make sure that all of this is written with one Fwrite call, since otherwise if two programs are accessing the pipe at the same time their writes could be interleaved.)

Here's a sample implementation:

```
---------------------- cut here -----------------------
/*
* runtos: a small program that will launch a TOS or TTP program
* in a TOSWIN window.
* To compile:
* gcc -O -mshort -o runtos.prg runtos.c -lgem16
* To run:
* runtos someprog.tos arg1 arg2 arg3
* OR
* Using the desktop, do an "Install Application" on runtos.prg.
* For "document type", use .TOS. Now, double clicking on a TOS
* program will automatically start it up in a TOSWIN window.
* (unfortunately, it will also cause all TOSWIN windows to be
* hidden -- you'll have to select "TOS programs" from the DESK
* menu to get them back again).
* BUGS
* See above. Also, it would be nice to have a "runttp.prg"
* that would prompt for .TTP arguments. This is left as an
* exercise for the interested reader. Reporting errors is
* also left as an exercise.
*
* "runtos" was written by Eric R. Smith and is hereby placed in
* the public domain.
*/

#include <minimal.h>

long _stksize = 2*1024;

int
main(int argc, char **argv)
```

```
{
/* BUG: shouldn't have a fixed size buffer */
static char buf[1024];
char *where = buf;
int i, fd;
long r;

if (!argv[1]) return 2;

/* first, put the path */
*where++ = Dgetdrv() + 'A';
*where++ = ':';
Dgetpath(where, 0);
if (!*where) *where = '\\';
strcat(where, " ");

/* next, put the program */
strcat(where, argv[1]);

/* finally, put the arguments */
for (i = 2; argv[i]; i++) {
strcat(where, " ");
strcat(where, argv[i]);
}

fd = Fopen("U:\\PIPE\\TOSRUN", 2);
if (fd < 0) return 1;

r = strlen(buf) + 1;

if (Fwrite(fd, r, buf) != r)
return 1;

return 0;
}
```

3732. MiNT library patchlevel 24 now available

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-04 05:30:49 UTC
From: ersmith@uwovax.uwo.ca
Message-ID: <1992Oct4.013049.1@uwovax.uwo.ca>
Source record: 42584
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've just uploaded a new version of the MiNT library to
atari.archive.umich.edu. It's patchlevel 24 (patchlevels
21 to 23 were "internal" releases :-)) and may be found
in Mint/mntlib24.zoo (library source code) and Mint/mntinc24.zoo
(header files). Compiled versions of the library will be uploaded
shortly.

This library is for use with several C compilers, as a replacement
for or supplement to their normal run time libraries. It will
produce executables that will run under either TOS or MiNT,
although multitasking features such as pipe() and fork() require
MiNT to be present to work properly. Compilers supported are:
GNU C, Pure/Turbo C, Sozobon C, and Lattice C.

Many thanks to Howard Chu (who contributed the GNU C -mbaserel
support for this version), Michael Hohmuth and Ulf Moeller (for
the Pure C support), and Jwahar Bammi (for numerous bug fixes
and enhancements).

Yes !!

Atari harddisks are generally decomposed like this:

ACSI to SCSI adapter (also known as host adapter)
SCSI to MFM (or RLL) adapter (also known as controller)
Hard disk (MFM or RLL)

As your harddisk is 20MB, it is MFM (the 30M is RLL)

The 2 different adapters are separated in (very) old drives but
not with 'new' ones.

So if you have 2 PCBs in your megafile, you have access to the
SCSI interface.

You can either buy an MFM drive and put it in place of your old
(but big MFMs are rare today), or add it as a second drive (you
have 3 connectors and 2 of them are connected to the
harddrive, the 3rd is unconnected (and resembles one of the 2 others
quite a lot): the unconnected is used for data transfer, the connected but
different is used for control and is shared by the 2 drives).

The last and best solution is only possible if you have access to the
SCSI bus:
You get rid of the second PCB (the controller) and your HD, and
you plug a brand new big and fast SCSI drive in the suddenly unconnected
connector (which sould be something like 2x25=50 pins I believe)

Stefan

PS: nothing is sure of I just said !

Hm. Diamondback has compression, and doesn't require a RAMdisk, but I
reccomend against that. With Turtle, you can restore from your backup
simply by copying the files up from floppy. With Diamondback, you have
to hope that nothing was damaged in any way. If it was, you're probably
hosed.

The memory is a problem if you have a 512K machine, but WHY? RAM is
cheap, and a LOT of software won't run in that limited space.

I was, at one point, frustrated with Turtle's lack of compression.
After using Diamondback, and watching it try to compress .LZH files (and
making them 10% larger each time), I gave THAT up quick. Turtle has
problems, but it's better than the others... (now if I only had a
floptical drive...)

Check out the terminalprogram ConNect (up to version 1.60 now I think).
It will let you use the MegaSTe's Modem 1, Modem 2, Serial 2, or Midi
ports. Modem 2 will go up to 153600 baud, and I believe Serial 2
will go up to 125000 baud...

Just so you know five sectors per track was actually a good idea. What difference does 1024 bytes less per disk make? One more thing-a FAT for a 850KB disk (85 tracks x 10 spt) needs more than a 3 sector FAT.

If you find such a list, could you tell us where you found it, or even
send the complete list to this group (or at least to me:)? If you don't
find such a list, please flood this group with your own findings...

3741. Spurious Interrupt? (Programming question)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-04 21:15:52 UTC
From: chuckies@cs.mcgill.ca
Message-ID: <1992Oct4.211552.26528@cs.mcgill.ca>
Source record: 42594
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I am writing a program which uses Timer A on the ST, as well as the mouse interrupt vector and a VBL interrupt vector. Sometimes, and at long, irregular intervals, I get an Exception 24 (spurious interrupt). Would anyone know what this means exactly and/or what to do to fix it? Any help appreciated.

Response by e-mail preferred...

Thanks.

Setting up your GCC environment:
Pick a location for the object file libraries.
Set the environment variable GNULIB to the full pathname
that you selected above.

Pick a location for the header (include) files.
Set the environment variable GNUINC to the full pathname.

Pick a location for the executable files.
Set the environment variable GCCEXEC to this pathname, plus
a "gcc-" prefix.

Example:
GNULIB=c:\gnu\lib
GNUINC=c:\gnu\include
GCCEXEC=c:\gnu\bin\gcc-

You can put gcc.ttp anywhere on your path, that program will use the GCCEXEC
variable to find the other programs that it needs. These include the assembler,
the linker, and the archiver. These programs are named gcc-as, gcc-ld, and
gcc-ar. They were given the "gcc-" prefix to avoid confusion with any other
like-named tools you might have on your system from some other programming
package. If you don't have any other such package on your system, you could

do away with the gcc- prefix (e.g., just rename gcc-as.ttp to as.ttp), then your GCCEXEC would only have to look like "GCCEXEC=c:\gnu\bin\". Alternatively, after renaming, you could just set c:\gnu\bin in your path and not worry about the GCCEXEC variable. (Obviously gcc needs more than just the assembler and linker; it has to know where cpp, the preprocessor, and cc1, the actual code generator, reside as well.)

In my MiNT configuration, I have a symlink to /bin, /lib, and /include, so I set
GNUINC=/include
GNULIB=/lib

|> Yes.. more questions for the tech guys..
|>
|> I was wondering if there are PD C library files for the Line A routines?
|> or.. should I bite the bullet and learn ASM?

Line A is a dead end. If you really need realtime graphics (for games/demos etc)
learn asm. Otherwise stick with vdi.

|>
|> also, I just found out, in my TOS book, that one pixel in lowres is
|> spread out over 4 bytes. I have heard of this before in other architectures.
|> but.. Why do they do this? Isn't it slower to do it this way?

Depends on the graphics operation. Having the bit planes separate means
you can use the same bit patterns in all resolutions - just copy them into more
planes - thus displaying text for eg is faster.
The downside is writing to individual pixels (as opposed to blocks of
pixels) is slower.

|>
|> I'd like to be able to manipulate bitmaps (rotations etc) but
|> since the pixel info is spread out, how to I convert these types of algorithms?
|>

Just apply the algorithms to one bitmap at a time. Of course if you want
to do operations that work on the whole value of a pixel (shading/
antialiasing/texture mapping) this fails.

|> i would assume that to get one pixel out of a graphics screen long word
|> would take 32 shifts and 4 long word masks. Am I underestimating the speed
|> of the 68000? it would seem that it would take a while (time that would add up
|> over a large bitmap) to compute.

Yes but if you're dealing with a large bitmap you can extract pixels in left
to right order _much_ more quickly.
I posted some code to do this a while ago - the trick is to use alternating
add.w & addx.w instructions for 1uS/pixel/plane + screen accesses +
looping overhead (which can be eliminated with linear code).

```
*
* planes 0 to 3 in registers d0 to d3
*
add.w d0,d0
addx.w d4,d4
add.w d1,d1
addx.w d4,d4
```

```
add.w d2,d2
addx.w d4,d4
add.w d3,d3
addx.w d4,d4
*
* d4 now contains 4bit value of leftmost pixel and planes have all
* been left shifted so that next time this code is run the 2nd pixel
* from the left will be extracted.
```

< stuff deleted >

Warren,

If it is _important_ for you to back up the data on your hard disk (i.e.,
you don't want to risk losing the data) then I strongly encourage you to
check out Diamond Back II and Diamond Edge from Oregon Research Associates.
While Turtle is a fine shareware program, it simply cannot compete with these
fine commercial utilities. If your local Atari dealer <grin> doesn't stock
them, you can reach ORA by phone at (503) 620-4919. They also frequent the
Usenet but I'm sorry, I can't seem to find their email address.

I'm not affiliated with ORA... just a happy customer. :)

From: grier@bnr.ca
Message-ID: <1992Oct05.183054.5749@bnr.ca>
Source record: 42607

I have replaced the internal drive on my ST with one from BEST electronics. The replacement was a 1/3 height drive that came with an adapter to place the drive at the correct physical height. The drive itself is a Teac drive. I would not expect any problems with replacing the drive with any other drive. Just make sure that the new drive has pin 1 in the same location. I've heard some real horror stories from people that have used drives with Pin 1 on the other side.

The problem is a follows: The boot sector on their hard drives gets trashed. Why? Well the DMA port and the floppy drive share data lines. If your new floppy drive has pin 1 on the other side AND you fail to notice this and fail to make sure cable pin1 meets floopy pin 1 your data/command lines to your ASCI port get asserted, causing hard-drive corruption.

So the moral is ... make sure you test with the HD NOT connected.

Brian.

From my GFA 3.0 manual, in the section on the SOUND and the WAVE
command:

The keyclick can be switched off by:

```
SPOKE &H484,BCLR(PEEK(&H484),0)
```

It can be switched on by

```
SPOKE &H484,BSET(PEEK(&H484),0)
```

BTW, bit 1 in the same location is the flag for key repeat on/off.

Hope you can use this,

It's rather plug and go !

The only problem I encountered (with 3 upgrades) is
mechanical: ctual drives are smaller, so that you may have
to add some fancy picec of anything to use place (to fix the whole)

There can be problems if the old floppy is single-sided, but
I don't know anything about it !

Hi-

I quite often see posts for old 10, 20 & 30 MB hard drive mechanisms on the net (not just in c.s.a.s[.t]) and have been wondering whether or not I might be able to make use of them.

I have a Supra 20 MB drive that I bought in about 1988 (it's not the early, early Supra, but not a real recent one either -- it's got a clock & the ability to daisy chain the DMA cable, I think).

What I'm wondering is, how easy (possible?) would it be to add a used drive mechanism to the power supply/case/adapter I've got now, to effectively double my storage capacity? What I'm thinking is, maybe, have C:, D: and E: partitions on my original drive mechanism (just as I do now), and have F: and G: partitions on the other... Something like that.

I understand that hard drives usually have extra room in them, as well as an extra cable & possibly enough of a power supply to drive more than what they came with. Am I totally mistaken? Is what I propose possible?

Thanks...
John

>The only problem I encountered (with 3 upgrades) is
>mechanical: ctual drives are smaller, so that you may have
>to add some fancy picec of anything to use place (to fix the whole)

Some MS-DOS drives are upside down at the connector interface. Quite
often the ST floppy cable is too bloddy short to turn it upside down.
It's a pain twisting it upside down. I think on an internal drive it
won't be a problem with the drive mounting as most of the drives are
four post drives. Unfortunately in very early SF3x4 external drives,
they used Epson drives and the cases were only drilled for their
three holes. The side with one hole caused problems as you had to
put in two new mounting posts where the mounting screws are at.

Also, if the fellow is having problems getting a drive, he can use
any of the 1.4Meg drives. I've heard 720K drives are hard to come
by these days.

(If you like please forward to the original poster. I can't post
onto the net itself,just email answers.)

Please reply by *E-MAIL*.
Here goes:

Is a C++ available for Atari. I have Turbo C++ v3.0 for the IBM platform, but would prefer to use my Mega 2 to edit files, compile, link, and execute them. I'm just starting with C++, so my programs won't be overly large (no more than 10K source code). Also, some documentation covering Atari specifics (GEM, AES, graphics modes, etc.) would be nice. BTW, I have Lattice verson 5.0, would the documention for its Atari specific stuff be relevent to C++?

Is such a beast available? I'm willing to buy a commercial program if it is well done and has extensive documentation. A shell would be nice too. I'm going to get Gemini from a.a, but a built in shell would be great.

Anyway, I'm looking for suggestions. If anything is at a.a, please specify all files that I will need. I do have a hard drive, so that isn't a problem.

Assume I know nothing about ST/STe/TT/Falcon/etc./etc. internals. You'll be pretty close to the truth of the matter. What book or books would you recommend getting?

adTHANKSvance,
Kenneth Love

|> worst case. Doesn't seem too bad.
```

I just can't resist optimising this code:

```
24 movep.l (a0),d1 ; get pixel data
8-24 lsl.l d2,d1 ; shift left to desire bit
4 moveq #0,d0 ; zero result
4 add.b d1,d1 ; get 4th bit
4 addx.b d0,d0
4 add.w d1,d1 ; get 3rd bit
4 addx.b d0,d0
4 swap d1 ; get high bytes
4 add.b d1,d1 ; get 2nd bit
4 addx.b d0,d0
4 add.w d1,d1 ; get 1st bit
4 addx.b d0,d0
```

Look Ma, no longword masks, no branches & only _one_ shift instruction.
Best case 72cy/9uS, worst case 88cy/11uS. Of course if you want to do consecutive pixels you should use the method I previously posted and get an average of ~48cy/5uS per pixel or 320mS/screen.

Steven

>I know how to set them with Rsconf(), but can't figure out how to retrieve
>the current values. One piece of code I saw (in the uupc.zoo file at
>atari.archive) suggested that Rsconf() returns this information encoded
>in a long, but no everything else suggests that Rsconf() is a void function.

The function indeed returns a longword with the previous values of the
rs232 registers in a longword, in the same order as they are specified
in the Rsconf call (excluding the baud rate), with the first UCR in
the high-order byte and the rest in decreasing order. You should call
Rsconf(-1, -1, -1, -1, -1) to retrieve this longword.

On TOSses AFTER TOS 1.04, you can specify -2 for the baud rate (first
parameter to Rsconf()) to retrieve the baud rate. I haven't tried
this myself as I have TOS 1.04 and it doesn't seem to do the right
thing (as a matter of fact, a -2 for baud rate crashes my machine.)

Cheers,

heneganj@cs.aston.ac.uk (Leavin' soon (sob)) writes:

>yo BUZ!

>erm, get a DECENT basic like STOS and you type CLICK OFF

>ha ha ha

I don't particularly like this kind of "helpfulness". First of all, calling
STOS a 'decent' basic means to me that you apparently missed something.
No flames, no discussion, all nonsense will be sent to dev/null.
Second, if you don't have anything to say, just don't say it please.

And now the original question: to turn off bell and key-click, just
POKE 10 at address $484. Turn it on again by poking 15 at the same address.
(note that 10 and 15 are decimal, $484 is hex and POKE is a byte-poke).

Hope this helps,
Hendrik Jan

I don't wish to be picky, but the "discharged of any static electricity" part above is nontrivial. Monitors can hold a lethal charge for some time after the unit is unplugged!! Discharging them involves grounding a screwdriver to the chassis, then pushing it under the rubber boot at the back of the tube (usually with a loud "pow!" as a result). I would not advise it to a novice. There can be some serious juice in there!

I suggest that you try playing with the connector (as the poster above recommends), and if that fails send it to a repair facility. Leave monitor guts alone unless you really know what you are doing.

3772. rolling your own ST hard drive

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-07 05:02:25 UTC
From: boyd@shmop.cs.fsu.edu
Message-ID: <1992Oct7.050225.14007@mailer.cc.fsu.edu>
Source record: 42631

I have been seeing a lot of hard drive questions lately, so I thought this would help. I post it about one a year, when these questions come up.

In article <bg258s1421.03a3@sycom.mi.org>, bg258s1421@sycom.mi.org (Burley Good) writes:
>I am looking for an inexpensive HD a starters HD. I am looking for a used
>maybe 20m or more CHEAP!!!

You might want to try rolling your own. It is very easy for the ST. You need:

A host adaptor
A power supply
An enclosure
A SCSI drive

I recommend the ICD Host adaptor. It has (IMHO) the best software, which is updated frequently (and available free). They also provide a very easy way to add a battery backed up clock to your ST (if you don't have one already, they can be bought with or without the clock). I also like ICD's because they report any "sense codes" the drive communicates to the user. I have only seen one ("read error with recover", induced by dropping something heavy on the desk while the hard disk was reading), but I find it reassuring that any weirdness at the device level is reported directly to me (it pops up in the corner of the screen, by the way). Price is about $80 at last look. Without the clock, you save $10. Order the SCSI connector cable whereever you get the host adaptor, and make sure to ask for a dual drive one with a red wire denoting pin one (to make the installation easier).

Power supplys are cheap. Just pick up an old XT power supply for ~$30 from computer shopper. If you can find a junked PC, you can get one for free.

Enclosures can also be cheap. You can buy one of those huge old style XT cases for about $30 from computer shopper. This will hold all the hard drives you will ever want! Buy a tower stand for $5 and stick it on the floor (the ICD cable is nice and long for this). You can also go all out and buy an enclosure which will fit under your monitor (mine houses 2 5.25" devices, has a front mounted lit power switch, mates perfectly with the ICD board, etc) with power supply for about $125. There are several places that sell these for the ST, two being Toad Computers and D&P Computer Supply. Email if you want their 1-800 numbers. Again, a junked PC is the absolute cheapest way to do this. If you can get ahold of granny's old IBM XT, you are in fat city. A nice side bonus is that the old PC motherboards make great wall hangings (big fat traces, lots of chuncky looking components). Old PC's are really easy to find, now that everyone is going to 80x86

machines.

Now, the SCSI drive. These can be bought from Computer Shopper. All you need is a bare SCSI device, no other boards or anything. The ICD host will work with just about anything, but there is a very large list of already tested drives that comes with the host adaptor (which I could probably email to you also). New drives are very cheap nowadays, but if you want to really save money you can get a refurb. Several of the refurb places will guarantee their drives for X number of years (X varies with the particular company), so they can be a viable way to go.

Anyway, you will now have your hard disk. You bolt down the drive and host adaptor (you can drill some extra holes in the case, or use wire-ties or whatever), connect the two, plug in the power cords (the ICD comes with a little splitter which connects to a standard PC type power cord), hook up the DMA, and boot up. It is very simple, and is not easily botched up. You only need to pay attention to:

SCSI id jumpers set to some reasonable value
SCSI terminator pack plugged into the drive (should come this way)
SCSI connector from drive to DMA is right side up on both ends
Nothing wiggling around

The first two can be checked via the manual that will accompany the drive (make sure you ask for it, some places assume you already have one), usually a 1 page Xerox. The third can be verified by checking that the red wire side of the ribbon cable is near pin one (which is marked on the board either by a number or by a square solder hole instead of a round one). If the cable is in backwards, the red end will be at the other end of the connection (quite often it is pin 2 that is marked, but you only need to know which end of the connector the numbers start on, and match it with the red wire). These are the only two possibilities. You cannot mess up the power connections or the DMA connection (they won't go in wrong).

The reason you wanted a dual drive cable is so you can easily add another device in the future. You merely have to plug it into the other receptacle on the cable, remove the terminating resistor pack off the middle drive on the cable (the one on the plug closest to the computer), and check to see that the SCSI id jumpers are set to two different numbers. Oh, by the way, the ICD supports the Syquest SQ555 (the 44mb removeable cartridge drive) without any special concerns. Since the Syquest is a SCSI device, you can hook one of these up just a easily as you could a regular fixed disk drive. These only cost about $320 bucks nowadays, with 44mb cartridges going for ~$60.

It really is easy, and there are plenty of computer tinkerers around to look over your shoulder and verify what you do. You can also use a setup consisting of a host adaptor, SCSI controller board, and ordinary PC type hard disks, but you add complexity to the system and lose performance this way. Straight SCSI is much cleaner, and usually much faster (SCSI devices have their controller boards "built in", communicating with the SCSI standard).

If you do get a hard disk, you should immediately buy Neodesk 3 and the Universal Item Selector III. They will make life much nicer. Also, beware of buying too small a hard disk. Megabytes are like potato chips. I have a buddy with a 105mb quantum drive, a 320mb Hitachi, and a Syquest SQ555 with 6 cartridges all hooked to his ST, and he still complains about not having enough disk space! I have not yet gone that apeshit, but I think Mr. Visa might have to talk to Syquest Corp. pretty soon. Oh, notice the my friend above has three SCSI devices hooked to his ICD. This just requires a 3 plug cable. The ICD can support 8 SCSI devices, and you can hook up multiple host adaptors if you really need to (like if you get given a box of 10mb SCSI drives :-).

Please feel free to email questions. The above is IMHO, direct flames elsewhere.

>its important.

Strange, the TEAC's are supposed to work with no problems. I put an arc file containing a bunch of floppy related hardware how-to's on atari.archive a couple of years ago. It was probably called ibmfloppy.arc, or something like that. Also, there is a software solution in fmc.arc (or lzh, stands for Force Media Change). Good luck.

In theory, yes. However, I would personally recommend getting an ICD host adaptor (to replace Atari's), and a standard SCSI mechanism. They should fit in the case, and I am sure you will be much happier with the speed and nice software. Host adaptor should cost about $80, SCSI's are pretty cheap.

3778. Re: XBIOS function to set floopy seek rate

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-07 12:40:22 UTC
From: bpat@cs.mcgill.ca
Message-ID: <1992Oct7.124022.11037@cs.mcgill.ca>
Source record: 42634

The ST boots up on the fastest speed it can effectively use. Slowing it down is pointless (Unless you are using some *OLD* & *SLOW* drive), and making it faster (Only 1 step higher is available) can only result in data loss. Really, leave this one alone, it's not worth it (Why did atari put it there anyways ???)

Patrick.

3779. ST Timer-B routine

Newsgroup: comp.sys.atari.st.tech

3780. Re: Are 100ns DRAMs too slow for an 1040ST ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-07 13:43:27 UTC
From: grier@bnr.ca
Message-ID: <1992Oct07.134327.6246@bnr.ca>
Source record: 42633

I've heard of this problem before. If memory serves me the problem is with your MMU chip and/or the 5vdc power supply. Some early MMUs can not drive 32 chips. Also if your 5vdc is below 4.7 volts some memories seem to balk.

My 520ST is upgraded to 2.5meg with a Z-ram board using 100ns chips. The only time I had a problem was when I also tried to use a Spectre GCR. The system sometimes wouldn't even come up. I replaced the power supply and everything works great now.

I would call BEST Electronics and ask them. They sell MMUs and better power supplies. I do not have their phone number here. I'll check at home.

>
>Does anyone know of an XBIOS call or a direct POKE that will turn the key click off?
>
>James Busby
>

In GFA, the poke would be either:

Spoke &H484,6

or

Spoke &H484,7

I'm not sure which. Here are the bit assignments for the first three bits
of that byte (accessed only in supervisor mode).

Bit Meaning
0 Key click on/off
1 Key repeat on/off
2 Bell on/off

Hope this helps.

> faster (Only 1 step higher is available) can only result in data loss.
> Really, leave this one alone, it's not worth it (Why did atari put it there
> anyways ???)

It's in there because the 5.25" drives require more time for
the head to move one track. I agree leave it alone for 3.5" drives.
However it must be set to 6ms for the 5.25" drives

Hiya. I just got my 4MB upgrade (a JRI+ board with the appropriate SIMMs) in the mail. The instructions say I'll need to disable the existing 512K memory (oh, almost forgot, this is an old-style, external-floppy 520ST). Well...

Once upon a time (1988), I had a "Ram Easy" 1MB upgrade installed for me. I imagine I'll have to disable / remove this as well, and since I've never seen it, I don't know what to look for.

If anyone out there is real familiar with this kind of RAM upgrade situation, could you e-mail me with a brief description of what I'm looking for and how to disable or remove it?

Buckets of thanks in advance....

3785. 1040 ST hardware problems

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-07 19:45:54 UTC
From: rvenable@helix.nih.gov
Message-ID: <1992Oct7.154554@helix.nih.gov>
Source record: 42639

I have an aging Atari 1040 ST, and I have some unusual minor symptoms:

- the sound no longer works; I had both the monitor and the Yamaha chip tested, and neither was the problem

- I can't boot with the cartridge for my hand-scanner installed

- the system crashes whenever I try to use the Install Application item from the desktop menu

I have TOS 1.4 (most of my games no longer work) and 4 MB RAM (EA Brown, I think)

Does anyone have any suggestions besides buy a newer machine?

Rick Venable

3788. TOS 2.06 & OXYD2 -> problems !?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-08 10:54:22 UTC
From: andi@gmd.de
Message-ID: <andi.718541662@gmd.de>
Source record: 42491

Hi, netters!

After upgrading my old 520 ST+ to 4MB and TOS 2.06 and supplying it with a hardware clock, I discovered the following problem with OXYD2:

When the menu shows up, there is a section in the lowest part of the screen where you can see some graphic symbols black on white overlaying the menu. When you start the game, this 'symbol-panel' starts flickering with every movement of graphic on the screen.
The game still works, but it's not much fun guessing what's happening below this 'panel'. The same happens with OXYD and SPACOLA, so it seems to be originated in this special kind of software.
Assuming a hardware fault, I went to my local dealer, who had done the upgrade. He checked everything twice and didn't find any defects. I guess it has something to do with the new TOS.

So I decided to post this query to the net. Maybe some of you had similar problems with this software and know a solution.

Thanx in advance,

Andreas Rohrschneider.

P.S.: STADT, a painting program from Application Systems Heidelberg also doesn't run anymore. I only get a messed-up screen and some bombs. Any suggestions ?

You shouldn't use a blunt Spoke, BTW, since this doesn't preserve the
settings of the other bits. You should use an AND with the original
value.

I don't think it's related.

What kind of drive and other hardware are in the Tulin case? ICD host I presume?

If you haven't already, back up the drive. Also try the drive on another ST if possible; I may be wrong about the STE not being related. :^)

According to the ICD ADSCSI CPX, sense $24 is an "illegal field in CDB" error, whatever that means. (Experts?) The drive may need formatting later on. In fact, I'd recommend it once you get your data backed up. Are you using the latest version of the hard drive utilities?

> Brian

The access time shouldn't be a problem:
I have one original 512K 150ns bank and one 2M 70ns bank

When I installed my 2M bank (with off-the-shelf parts like SIMMS
and simm-sockets), I've had similar problems although the MMU
wasn't the problem.

In fact, the problem was power supply, and particularly cables.
Don't try do save money limiting cable size (diameter) and number
for power. It's much safer to have 2 GND and 2 Vcc cables !!

Since I added that second pair of power cables, I haven't had any more
problems !

Stefan

I suppose you have set GCC_EXEC_PREFIX. There is a bug in the Compiler-
Driver gcc. I have compiled a fixed version for the ST. It is located
at ftp.uni-muenster.de in the folder pub/atari/Gnustuff/Gcc/
The filename is gcc222b3a.zoo.
--
!"$%&/);=?!-.'"[!=({\,@*~#+$['&^(/!&=]`"%$_^.|?>}`>|"/~^<$:&)*;#!;[&=#"&%$\':"[
" Bjarne Pohlers Fast address: <pohlerb@math.uni-muenster.de> &
[":'\$%&"#=&[;!#;*)&:$<^~/"|>`}>?|.^_$%"`]=&!/(^&'[$+#~*@,\{(=!["'.-!?=;)/&%$"!

Even better, don't use GCC_EXEC_PREFIX at all on the ST. Since I've
been using GCC, which is since version 1.36 (over 2 years now), I've
set the variable GNUEXEC (similar to GNUINC and GNULIB). Please don't
create another version of GCC 2.2.2. There are already three, I know
of (Bammi's original, Howard Chu's version with baserel and a version
here in Paderborn,Germany compiled with MiNT libs).

I would definitly suggest, to stick with J.R.Bammi as main maintainer
of GCC (until he decides to pass the key). I'm sure the last changes
from Howard will move into Bammi's version.

Another technical reason to not use GCC_EXEC_PREFIX (or fiddling with
it) is in a cross compiling environment. GCC_EXEC_PREFIX is then used
the access the native machine componente of GCC and GNUEXEC is used to
locate the ST cross compiler equivalents.

BTW, Bjarne, this is also my main criticism to your article in
ST-Magazin.

Source record: 42505

How would I go about detecting if an accessory was closed (after it had been opened, of course) while a GEM application was running? The message pipe never seems to return AC_CLOSE (or AC_OPEN), which, as I'm told, are only received by accessories. I tried WM_NEWTOP and no go (What the hell is WM_NEWTOP anyway? Never seems to be sent to my APP at all). Any ideas?

Oh ya, basically, I want my app to check the clipboard everytime an accessory is closed (to see if it contains some relevant data that I may have copied to it from STeno or STalker).

Thanks to all who help!

3800. GEMDOS calls within HSPascal

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-09 08:03:54 UTC
From: genius@sys6626.bison.mb.ca
Message-ID: <858csB3w165w@sys6626.bison.mb.ca>
Source record: 42504

Is there anyway to make GEMDOS calls directly from within HSP?
Basically, I want to be able to rename a file...but HSP has (as far as I can tell) _NO_ way to do that! I can't even say GEMDOS(xx)... as GEMDOS() isn't defined in any of HSP's units!

Thanks to any who help!

Actually it's "GCCEXEC" and not "GNUEXEC" but the other two are
correct. Since this can be a point of confusion I thought I'd
clarify...

>create another version of GCC 2.2.2. There are already three, I know
>of (Bammi's original, Howard Chu's version with baserel and a version
>here in Paderborn,Germany compiled with MiNT libs).
>
>I would definitly suggest, to stick with J.R.Bammi as main maintainer

>from Howard will move into Bammi's version.

I certainly agree on this point. There is already enough confusion
(evident from the ever-recurring "how do I run GCC on my ST?" posts)
and I have no desire to add to it. I have sent all of my changes to
JRB, so they should be a part of his next patch set. What I've made
available was never intended to be more than an interim release, for
the more impatient folks to use until Bammi's release came out.

That should also be clear from the Readme files included with those
archives, but this is a good time to reiterate - as far as I'm concerned,
Jwahar Bammi is the only "official" source for GCC for the ST. The
changes I made start from his patchlevel 3/update 24 set, and unless
they appear in a patchlevel 4 set, I would not consider them "official"
in any way, and neither should you. You *definitely* should not
distribute changes of your own based on my source code; that will only
create more confusion. Jwahar has done an excellent job of providing
consistent and orderly management of the ST port and I would hate to
see his efforts undermined by my own over-eagerness or anyone else's...

3802. Using RBG/Sync monitors with ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-09 10:06:10 UTC
From: Bill_von_Hagen@transarc.com
Message-ID: <8epJaGr0BwxT8Mqlw6@transarc.com>
Source record: 42506

I posted this on the standard atari.st bboard, but didn't receive any useful info yet. Perhaps someone here could help me.

I have a Sony Trinitron monitor (GDM-1601) which I'd like to try to use with my ST. It has RGB and Sync inputs - the sync inputs are labelled HD and VD. Could someone tell me if there's some add-on hardware I can get for the ST so that I could use this monitor with it? The monitor is also used with a MIPS workstation, but I'm just interested in experimenting.

Thanks!

Bill (wvh@transarc.com)

I don't know if I've misunderstood your question, but you simply have to make sure that whilst you're writing on the last screen line you don't
a) send a newline
b) write characters past the end of the line

a) is easy to avoid, and you can sort b) out via the vt52 emulator - I think you need to send a \033v to tell it to ignore characters that go past the end of the line.

If you want the user to input on the last line, you'll need to write your own input routine that doesn't echo any characters from the users input except those you allow. Easy enough to do, but if you want mail me and I'll send you something suitable. My editor has two functions for writing to the bottom line, void *write_minibuffer(char *string) for simply printing status info, and char *prompt_minibuffer(const char * prompt, char *input) for getting user input via the status line. Both store cursor position (via vt52) on entry and restore it on leaving, so the caller can forget about these details. Again, if you'd like them then mail me. They're in C, btw.

>ideas?

My (not completely blind) guess would be that this is not possible, but I
could be mistaken (if so, please let someone correct me). According to
the 'Atari Profibuch' WM_NEWTOP is the same as WM_TOPPED.

If my above conjecture is right, then maybe you could try the following
work-around: include a timer-event in your evnt_multi, so every once in
a while you enter your event loop, even if there are no messages for you.
Then look which window is topmost and check if it's one of your windows.
If not, apparently some acc has a window open (ignoring the possibility
of multitasking environments). In this case you set a flag (AccOpened=1).
As soon as one of your windows is topmost and the flag=1, it *could* be
the case the acc's window was closed (or one of your windows was topped
of course - but this could be checked too - probably with another flag :).
Then reset the flag to 0 and do whatever you want to do (i.e. inspect the
clipboard).
I don't know if this works - I'm making this up while I'm typing...
And if it works, it probably needs some 'sophisticating' - I guess the
above is only a very crude outline, but I suppose you get the idea.

... well, it doesn't sound *that* bad, does it...? :)

I'm using Prospero C and I need to be able to truncate a file at a certain offset. I can't see any immediate way to do this, can anyone suggest a solution?

3809. Comparing Strings in 68000 Assembly

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-10 00:03:30 UTC
From: mcarrico@terapin.com
Message-ID: <mcarrico.1tqa@terapin.com>
Source record: 42510

I'm a programmer in various different languages on the ST, but one langauge I am learning at this point is 68000 Assembly. I think I have the hang of reading single characters and printing them to the modem or to the screen.

I am working on a project that started out as a "Chat Mode" program for a friend of mine, for his BBS, and after he found a program, I decided to make it into something different. I have a small VT52 Terminal Emulator program written in Assembly langauge. I talked with my friend and we are discussing taking that program and re-arranging it so the single key routine reads a string instead. The over-all goal is to make the chat mode one procedure in an online adventure game..I.E. The Local sysop can interrupt the player with say the F1 key.. and chat with him..then hit it again and the player resumes playing..anyway I'm finished with the Chat mode part, but now we need a routine that can read a string and compare it with some common commands, such as "North" or "Look" or "Open Door" These type..

Anyway, I found some routines to read a string using GEM, but it does'nt trap control C, so I decided to attempt to write my own variable length readstring routine. It takes one character at a time and adds it to a buffer, then when the user hits return, it ends adding to the buffer, and compares the buffer to the string I want.

Well I pretty much have the readstring part, but as soon as I compare the string..(exit from inputting) I get 2 bombs and it exits.. Addressing Error.

Well.. Here's the string compare assuming A1 holds the starting address of string 1 and A2 holds the starting address of string 2..

This is my compare routine..can someone please give me a hint as to want I am doing wrong?

```
==========================================================================

ST D6 ;Set $FF to D6 we are using this as a True/False Register
CLR.W D7 ;Set $00 to D7 we need a clean slate for a character counter
LOOP CMPM.B (A1)+,(A2)+ Compare the bytes of each and increment pointer
BNE MISMAT If they are different, then string does'nt match
TST.B -1(A1) Did we reach a Null Byte ? (End of string)
BEQ ENDOK If we did then both are null, so end..
ADDQ.W #1,D7 We tested one byte so far, so add 1 to the count!
BRA LOOP Branch back up and loop
MISMAT CLR.B D6 Strings don't match so make D6 False ($00)
ENDOK ... We continue here
```

Ok soo using that I should be able to compare byte by byte right?

What am I doing wrong?

ST MASTER

I had this problem as well. To solve it, you have to use the Line-A variables, which would make your program TT-unfriendly. And most likely Falcon-unfriendly as well. So if you go ahead, make the status bar optional so that users with TT systems are not left in the cold. To actually do it, you:

To further complicate matters, I found that I could not access the Line-A variables through Personal Pascal so I had to play with the memory locations themselves, which is not a good thing to do. Anyway, the WORD located at $2AB2 holds the number of lines that the screen is. After you get the original value, subtract one from it, and then put the value back via the poke() function appropriate to WORD values. When you want to change the line, simply add one to the value, poke it, do what you need, subtract one, and poke the value again.

Keep in mind I have only tested this on TOS 1.4, and it IS NOT GOOD PROGRAMMING PRACTICE TO BEGIN WITH. Regardless of how I did it, though, at least you now know that you need to use Line-A to make the screen shorter.

One user suggested another method, which was to re-write the VT-52 handler that the computer uses. This was beyond me, but I was told that there was a much better (and faster) VT-52 handler at atari.archive (which I have no access to so I could not verify).

I hope this information helps you out a little.

TC> How would I go about detecting if an accessory was closed (after it
TC> had been opened, of course) while a GEM application was running? The

You can't under normal circumstances; the accessory would have to send a message explicitly to you. The idea of accessories is, that they do not bother the main application at all, and they are therefore "invisible." There is a protocol called XACC, which provides for communication between applications and accessories. I only have the German docs, which I can mail to you if you want.

TC> message pipe never seems to return AC_CLOSE (or AC_OPEN), which, as
TC> I'm told, are only received by accessories. I tried WM_NEWTOP and no

Correct.

TC> go (What the hell is WM_NEWTOP anyway? Never seems to be sent to my
TC> APP at all). Any ideas?

WM_NEWTOP is only implemented newer TOS versions, if memory serves me right. I can't remember offhand what the differences are with WM_TOPPED.

TC> Oh ya, basically, I want my app to check the clipboard everytime an
TC> accessory is closed (to see if it contains some relevant data that I

1) your program will have to check which line the cursor is on before echoing
it. You must then keep track of ALL characters coming in (And take care to
work with various ESC sequences that may move the cursor around)

2) If you are at line 20 and you want to add a line, then do:
ESC-Y-(32+24)-(32+79) {That's to place the cursor at the last
possible place}
(13) {To scroll up one line}
ESC-Y-(32+20)-(32+0) {place at first char of input line}
ESC-L {insert a line}
ESC-A {go up}
echo whatever you want ...

This will cuase the whole screen to go up one line, and then the input line
will scroll down one line. You can then echo whatever you want.

If you need a list of the vt52 escape sequences, just ask me. (like reverse
video for some information line)

Hope this helps.

Patrick.

Ok, between Kevin and Michel I've gotten a good start towards wehre
I need to go but, I still haven't quite gotten it. Michel suggested
that I ues the Line-A function but, he suggested it in Pascal. I
should have said before that I'm using C. I looked thru my libraries
on Line-A functions and I didn't find *anything* on how to shorten
the screen which is what I'm trying to do. Let me try and explain
waht I'm trying to do a little better. Whenever there is input on
line 20 I want it to be on line 20, when input comes in for the next
line (line 21) I want the screen to scroll up and have the input displayed
on line 20 again and so on and so on. I'm using Laser C and as I've
said I've looked thru all my functions twice over. Michel I think
suggested that I Peek and Poke a location but, I don't think I can do
that in C... any suggestiosn will be greatly appreciated.

Alex

um, so that you know, the ST has a built-in vt52 emulator. I mean, everything
you send to the screen is processed as if it were a vt52. (at least by GEMDOS
when you use 2 as output device. Using 5 will turn vt52 off)

>in Assembly langauge. I talked with my friend and we are discussing taking that
>program and re-arranging it so the single key routine reads a string instead.

There is a GEMDOS function for that. It's called READLINE

```
pea buffer
move.w #$0A,-(sp)
trap #1
addq.l #6,sp
```

and the string will be at the address buffer afterward. It does interpret
^C (It causes the program that called READLINE to terminate), as well as
keys like backspace and tab. Of course, this terminate on ^C stuff might not
be good, so doing your own is probably the way to go.

>ENDOK ... We continue here
>
```

I must admit I'm puzzled as well. This routine by itself should work ok.
It's probably that you call it after calling GEM. There is one VERY important
thing to remember in assembly if you use the OS:

GEM (VDI or AES) will destroy d0-d3 and a0-a3.
GEMDOS, BIOS and XBIOS will destroy d0-d1 and a0-a1

So you should make sure that the values in those registers when you call your
string compare loop are yours, and not those GEM put in it, or else ...

Another thing might be that you did not pop the stack enough after some
GEMDOS, BIOS or XBIOS call, and a rts is reached inside your code.

If you'd like, you could send me the code (Or just the part that does all
this string input and compare if you prefer), and I'll take a look at it.
One thing for sure, the compare routine ain't at fault here.

```
>Ok soo using that I should be able to compare byte by byte right?
>
>What am I doing wrong?
>
>ST MASTER
```

I'll second this recommendation. I think there is a definate limit on the
size you can expand a Megafile 20 to anyway. And it's much lower than ICD's
2 or so Gigabytes (like probably 90M).

Line-A is dirty and shouldn't be used - except maybe when writing very machine
specific fast graphic demos and such... Easiest solution IMO: print the status
line (or whatever it is that you want on the last line) on *top* of the screen
instead of at the bottom. No need to make the screen shorter - just re-print
the topline everytime the screen scrolls up. When using Cconws and not printf()
this will be fast enough to prevent irritating flicker in normal applications.

p>I have a little problem with getting gcc2.2.2 to work.
p>gcc -v -c mytest.cc results in:
p>
p>gcc-cpp.ttp /d/gnu/atariST/2.2.2/ ...
p> /d/gnu/atariST/2.2.2/: file not found (not exactly gcc's message)
p> /* /d/gnu is the working directory */
p>
p>Do I need some new evironment settings ?

Unfortunately you didn't mention what env vars you've actually set, so I can
just guess what may be the problem.

I'm using gcc 2.2.2, and I can reproduce your problem, if I do set the env var
GCC_EXEC_PREFIX and I do NOT set the env var GCC_EXEC. Then I get the same
error message.
When I set GCC_EXEC and do NOT set GCC_EXEC_PREFIX then it works fine.

Maybe that helps.

3821. gcc2.2.2 cross-compiler

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-11 17:39:38 UTC
From: terjeve@ifi.uio.no
Message-ID: <TERJEVE.92Oct11183938@kolsaas.ifi.uio.no>
Source record: 42524

I just downloaded the source for gcc2.2.2 from a.a and have made
myself a cross-compiler (hosted on a Sun Sparc, SunOS 4.1.1).

When I compile a program with the -mbaserel option, the program
crashes with 4 bombs as soon as it starts.
But if i omit the linking on my cross-compiler and link the program
with gcc2.2.2 on my ST instead, the program works perfectly.

Both linkers are Patchlevel 31.

Help! :-)

I have an old Atari 1040STf. I would like to upgrade my machine from its original 1 Meg configuration to its maximum limit at 4 Megs. I am interested in the various ways to get this accomplished, such as piggy-banking chips, installing a ram board, etc. Are there any other cheaper/easier solutions? Are there any documentations on an FTP that can supply me with this information? I am pretty knowledgeable in electronics and reading schematics. Any help will be greatly appreciated.

Message-ID: <9210111750@jacom.UUCP>
Source record: 42461

Hi out there,

I have my Atari (1040) running about 4 meters next to my monitor (SM124),
but the monitor doesn't work the way it should. White points are shown
up 'too late' i.e. if there is a background like the desktop, where black-
points are close to whites, the whites points are ignored and the whole
background is black. I think this is due to the shifter, that is doesn't
raise the monochrom-pin fast enough to 1Vss... Does anyone know how to
'help' the shifter (yep, I don't have a blitter :( ). Is it possible to
bye an interface or something like this?

Thanx in advance, Joerg

3824. Mega STe HD problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-11 22:49:34 UTC
From: winfrvk@dutiws.tudelft.nl
Message-ID: <2209@dutiws.tudelft.nl>
Source record: 42531

Hello all,

A friend just bought a new Mega STe 2, 48Mb HD from a store that went
out of business. The machine is not _that_ new, because it still has
TOS 2.05, but okay, the problem is: The harddisk doesn't work right.
Symptoms:
- Sectors take seconds to load, or give an error.
- Reformatting doesn't help.
- Leaving the machine switched on for half an hour and trying
again _used_ to work. This was when it couldn't boot properly.

I'm hoping this is a known problem with an easy solution, because we don't
get any warranty.

Thanks in advance, Bart.

They are! An APP will never receive such a message.

>Oh ya, basically, I want my app to check the clipboard everytime an
>accessory is closed (to see if it contains some relevant data that I may
>have copied to it from STeno or STalker).

If you have the Sources let the ACC send a user defined
message to the APP if it receives AC_CLOSE.
If you havn't write an ACC which checks the Clipboard in
regular Intervals an does the above.

Where did you get this information (about the location) from?
And, is there also a location where the number of characters per line for the vt52 is stored?
I ask this question because I typed in a program called BIG_PIC, which was published in GFA basic in the c't magazine over a year ago. It demonstrates how to re-direct VDI output to a virtual screen of arbitrary size and color mode. The methods this program uses are not "clean" (does anyone know if the GEMDOS driver called MEMORY.SYS is available yet?). But it works, except for the fact that a CR-LF causes the cursor to be positioned a half line downward on a virtual screen of double width. Can anybody tell me which location needs to be manipulated?

I doubt it, Patrick... The EOF is a valid character too, especially if the file is a binary file. Also, the actual file size wouldn't be changed... And finally, on the ST, EOF is (-1) (i.e. 255), NOT ^D (too much UNIX these days, eh?)

Nope, the only way I can see is to open the file for reading, create another file for writing, copy n bytes, close both files, unlink the first, rename the second...

Of course, you can always try and figure out how to do this using the actual disk FAT, etc... but good luck...

Charles

>Syquest owners do?

I have had a 44 meg for over a year. I leave the disk in the drive almost
all the time, and the drive running. I haven't had any problems except that
after a little less than a year, my first cartridge started to stall if I had
turned off the drive and the powered it back up. This seems to be a cartridge
problem, as other cartridges start fine. Also, after I moved my news system
to another cart, and ran the new cart for a while, It stated to do it too.
But to make matters even more bizarre, the original cart started working fine
again. SO I just switch between the 2 cartridges when one gets fussy, and
everthing appears to be alright. Ejecting the cartridge when not in use and
keeping it in the box would probably be the best way to go, but not possible
when your news system does a lot of work at night.

> the 'Atari Profibuch' WM_NEWTOP is the same as WM_TOPPED.

No, they are different, but I am given to understand that WM_NEWTOP is only implemented on newer versions of TOS (1.2? 1.4? ...).

As I understand it, WM_TOPPED is sent to an application to indicate that one of its windows (ID given) has become the top window, and WM_NEWTOP is sent to an application when one of its windows stops being the top window because another window has been topped. In other words, a window is only on top after getting a WM_TOPPED until it gets a WM_NEWTOP.

Hope this is right - someone correct me it not. I think the information came from Tim Oren's 17-part Gem class articles, in a Q-and-A section.

Tony.

The driver 'MEMORY.SYS' is included in the atari FontGDOS package, which can be found on a.a.
But my question is: how do you use it? I guessed (and hoped) that it would allow VDI to be used on arbitrary blocks of memory.

I hope someone knows,
Bart.

> Alex

So you want a sort of seperately scrolling area on the last two lines, eg
given the inputs line1, line2, line3 and line4 in that order, the screen would
first display line1 on screen line 20, the line2 on screen line 21. Then when
line3 comes in, line1 will disappear from the screen, line2 will move to
screen line 20, and line3 will be on screen line 21. Similarly for line4, etc.
Is that right? If so, you can do this using the vt52 delete-line function.
Move the cursor to the start of line 20, delete a line, move down a line, then
print the new line, eg

```
printf("\033Y%c \033M\n%s",(char)(19+32),new_input_string);
```

(It may not be \033M, BTW). It is fairly easy to expand this to allow for
status lines in the middle of the screen and all sorts of cute effects.

Except that VDI output has nothing to do with the line A variables. Try dividing the size of your window by the size of a character cell.

Kev

I remember in the docs that came with my 44meg syqyest it said never to leave a cartridge in the drive when you power down. I never leave one in for long periods of time, though if I'm just going away for an hour or so, I'll disengage the heads (via the button on the front), and leave the cartridge in. I guess this is pretty close to being parked anyway, but there may be a problem with dust being able to get in (???)

> Where did you get this information (about the location) from?
> And, is there also a location where the number of characters per
> line for the vt52 is stored?

Before everyone starts swapping "peeks" and "pokes":
Michel gave the location *for one particular version of TOS*. I would be very surprised indeed if it is the same for all versions of TOS; in fact, it may even be different for different language versions of the same version of TOS. The line A variables have never been guaranteed to be fixed in one location.

The number of characters per line is stored at offset -44 from the base of the line A variables, and the number of rows on the screen is at offset -42. Actually, both of these are 1 less than the number, i.e. for an 80x25 screen linea0()-44 will hold 79 and linea0()-42 will hold 24. How you get the line A base address depends on your language/compiler; in C, with the MiNT libraries, you do:

```
#include <linea.h>
base = linea0();
```

Using these variables to change the number of lines (e.g. to provide a status line for a terminal program) is quite dodgy. It will almost certainly break under MultiTOS, for example, or under MiNT+TOSWIN (where your program is no longer running on the whole screen, but rather is in a GEM window).

Someone suggested using the top line as a status line -- that's probably the easiest "clean" way (you just let the top line scroll off and then redraw it). Even better is to put your program into a GEM window and manage the VT52 emulation yourself, but obviously that's a lot more work. (It does have the advantage that once the basic code is written, changing it to do VT100 or some other emulation would be quite easey.)

Im Artikel <mattera.718559744@turtle21> schreibt mattera@rtsg.mot.com (Michael Mattera):
> Are there any articles that give the Falcon's Spec's?
> What magazines are they in? Do the Atari dealers have

Yesterday I saw a 4-side Paper here in Hamburg (Germany) in the computer-
corner of a store, published by Atari Germany/Swisse/Austria about the
FALCON030 :

- system - CPU: Motorola MC68030, 16Mhz, intern Cache
- FPU: socket for optional MV 68881/68882
- RAM: modul-socket for 1, 4 or 14 MByte
- ROM: 512 KByte
- BLiTTER: co-processor, ST-compatible, 16 MHz

- video - video-subsystem for VGA, RGB and TV, extern
synchronisation for GENLOCK
- VGA: 640x480x256 colours from 262.144
320x480x65.536 colours
320x480x32.768 colours with Overlay-Bit
- RGB/TV: 768x480x256 colours from 262.144, interlaced
768x480x65.536 colours interlaced
768x480x32.768 colours, interlaced with
Overlay-Bit
- All ST-Modi, 640x400 s/w 71 Hz
- Hardware Overscan option
- Hardware Scrolling all modi

- Coprozessor Subsystems - Digital signalprocessor Motorola
DSP 56k, 32 MHz with 32kx24 Bit
SRAM, 0 Waitstates
- BLiTTER Coprocessor 16 Mhz ST-compatible

- Devices - Parallel port
- Modem/RS232
- MIDI in
- MIDI out/through
- Cartridge Port
- SCSI-II (50-Pin-Connector) with SCSI-DMA
- LAN Local Area Network (compatible with TT/M-STE)
- Mouse

- Sound - 16 Bit Stereo AD and DA in CODEC
- In for stereo-microphone
- Out for stereo-headphone
- Speaker (mono)
- Mulitiplexer for DSP, CODEX and Sound-DMA

- 8 channel 16 Bit DMA call and recall up to 50 KHz
(CD 44,1 KHz)
- Stereo 8 Bit PCM DMA Sound (compatible TT/M-STE/STE)
- 3 channel PSC-Sound (ST-compatible)
- IN/OUT for Digital Audio and DSP

- Joysticks - 2 STE compatible joystick-ports
- 2 standard-joysticks

- Floppy - 1.44 MByte Floppy (PC-compatible)

- Harddisk - intern optional IDE Harddisk, 2.5''

- Keyboard - (you know it from the 'good old ST' ..). The text
tells something nasty ;-)

- Mouse - 100 dpi

- Also - Battery-buffered clock
- Intern BUS with all CPU, Bus-control, Interrupt and
tact-signals
- Intern RAM-Bus

PS: In the text there is mentioned MultiTOS as the operating-system for
the FALCON030 !

3845. Re: Line-A variables

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-12 18:59:11 UTC
From: Cford@debug.cuc.ab.ca
Message-ID: <1992Oct12.185911.21702@debug.cuc.ab.ca>
Source record: 42464

Someone here was talking about the Line-A variables. First of all, I'd not suggest using the Line-A variables; if you do your programs will not run on a 68020 or better.

The Line-A variables are available relative to a location stored somewhere in RAM. I'm not sure exactly where, since I use GFA-Basic and in GFA the variable is L~A. Anyways, the number of lines the screen has is the longword
located at L~A-26. The number of columns is the longword located at L~A-28.

(Got this information from the GFA Basic 3.5 manual, page 471, Chapter 12: Appendix. From what I remember it is correct.)

Yes, but GCC_EXEC_PREFIX is documented in ``Using and Porting GCC'' - and
there is really no reason, why GCC_EXEC_PREFIX should not work on a ST.
Please don't
>create another version of GCC 2.2.2. There are already three, I know
>of (Bammi's original, Howard Chu's version with baserel and a version
>here in Paderborn,Germany compiled with MiNT libs).
The version at ftp.uni-muenster.de should be identical to Bammi's
original. (It was built with the help of the patches in updates21-24).
The only exeption is the fixed compiler-driver gcc. (It was a very small
bug, there had just `-imacros' to be replaced with `-iprefix'). This bug
was already reported in gnu.gcc.bug and will hopefully be fixed in the
next version of GCC.

>I would definitly suggest, to stick with J.R.Bammi as main maintainer
>of GCC (until he decides to pass the key). I'm sure the last changes
>from Howard will move into Bammi's version.
I agree. But as GCC is released in source-form, there is nothing
wrong about recompiling it.
>Another technical reason to not use GCC_EXEC_PREFIX (or fiddling with
>it) is in a cross compiling environment. GCC_EXEC_PREFIX is then used
>the access the native machine componente of GCC and GNUEXEC is used to

>BTW, Bjarne, this is also my main criticism to your article in
>ST-Magazin.
Well, I did not write an article about building a cross-compiler of GCC.
GCC_EXEC_PREFIX is documented by FSF and therefore it must work. And if
it doesn't, then it's a bug.

Regards, Bjarne

i think it was discontinued. It was intended as a way to inform app to store screen contents prior to being over written, applications that is that don't buffer the screen. i don't know why it was discontinued , but i guess it was to disuade people from writing to screen in the first place. "Thou shalt go through the VDI or be doomed !"... :-)

Ah, sorry about that. You just *think* both linkers are the same patchlevel, I forgot to change the version string in the linker binary that I uploaded. It is most definitely beyond level 31, and as I mentioned in the Readme files, you cannot use an older linker to link the baserel code.

But never fear, Jwahar Bammi's update25 is now available, so you can get the full set of assembler and linker diffs as well.

>whether you like it or not.

Not true. You get WM_TOPPED when the user wishes to top a window. My Edith
doesn't top background windows if the top dialog has to be finished first.

>>WM_NEWTOP (29): The window was activated. Seems to be identical with
>> WM_TOPPED (21) !
>> mbuf[3]: window handle

>the user clicked on you. do you want to be nice and go on top, or tell him to
>forget it because you're comfy where you are?

Not so. This one is not implemented in Atari GEMs. I assume this message was
actually meant to give ALL applications a sign if ANY window was ACTUALLY
topped by means of wind_set(w_h,WF_TOP,w_h). Really, it's too bad something
like that doesn't exist.

I never heard of

>>WM_UNTOPPED (30): The window will be inactivated (sp?) in a while. This
>> message can be used to buffer the contents of the window
>> somewhere in advance.
>> Only with GEM >= 2.0!
>> mbuf[3] window handle.

Now that would be great. You could use that to `backgroundify' your window. But
be cautious! In (not very distant-) future TOSes one can move, slide, close
etc. background windows! Especially the sliders are dodgy and will cause many
programs to write in windows of other applications.

Yes, wrong program. At the moment there are two drivers which support XHDI.
Both are from german developers. These drivers are HuSHI (included with the
SCSITOOL hard disk software from Hard & Soft Herberg) and HDDRIVER (included
with the disktool DISKUS from Creative Computer Design CCD or together with
the virtual memory manager OUTSIDE from Maxon Computer GmbH).
There are no other drivers that support XHDI at the moment.

3857. Lharc source?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-13 12:08:18 UTC
From: richard@op.ph.ic.ac.uk
Message-ID: <1992Oct13.120818.26420@sol.ctr.columbia.edu>
Source record: 42455

Can anyone tell me where I can get hold of the source for Lharc?
Most atari stuff seems to be lzh'd these days, and why not? It's
just that unlike arc or zoo, a unix version doesn't seem to exist and
I'd really like to look at some of the stuff I pull across, *before*
laboriously copying it to floppy and then finding out when I get back
to my st that it's not what I wanted :-(.

Thanks
Richard

There do exist an UNIX version of lzh, even the new lh5
version.
Here is an old article from comp.sys.atari.st :
(There is a little problem, the man pages are in kanji, but
there may be other sites with the program....

Organization: Delft University of Technology
Lines: 22

Hello all,

I have been using a UNIX lha which understands lh5 archives for a couple of months now. Unfortunately, I forgot where I got it from, so I did 'archie lha'

And guess what: the very first site it comes up with contains the version which I know works with Quester-generated lh5 archives.

Host akiu.gw.tohoku.ac.jp

Location: /pub/unix
DIRECTORY drwxr-xr-x 512 Apr 1 17:44 lha

I would be happy to put it on atari.archive if someone mails me the proper procedure (like where to put it and who to inform).

Let's hope this settles the (incorrectly named) lz5 war.

The icons (and other objects) are children of the root -i.e. the desktop-box.
So when you install a plain G_BOX as desktop, the icons won't be drawn,
since they're not childeren of your g_box.
I don't know how to use WF_NEWDESK when replacing the normal desktop - I
don't even know if this can be done in a simple way. Using WF_NEWDESK to
install a custom-made desktop in your own programs is rather straightforward
though.

>
>Is it possible to get better quality phonetics, or at least generate more
>human-sounding sounds?

I was wondering whether the following would work: Sample (using the mic. input on the Falcon, for example) every phoneme that a speech program needs from your own voice. (And change the pitch using the DSP whenever required). Then have it use the sampled ones instead of trying to create them by itself. It should'nt even take up too much memory. Looking at STSPEECH, there does not seem to be too many different phonemes. Say 32 or so, times 1/8th of a second each makes about 4 sec. of digitized sound to keep in memory, fiddlesticks.

In any case, as soon as people get their hands on the Falcon, you can be sure we'll see lots of interesting goodies taking advantage of the DSP and the Falcon's DMA sound.

Questions:

1) Does anybody know where one can contact the person who wrote ST Speech

2) How about a program for the DSP which will decode NTSC signals and let us watch Video's using the Falcon's monitor, inside a GEM window?

Does anyone know of a free source of BIOS documentation? I would like to be able to program my own exception handler for things like "disk drive not ready" or "general drive failure error". Alternatively, I wouldn't mind if I found some sample source code to look at. I would prefer C (or some other high-level language), but from what little I know, it's possible the only way to do it is in assembly language.

Thanks for any help ...

>could be mistaken (if so, please let someone correct me). According to
>the 'Atari Profibuch' WM_NEWTOP is the same as WM_TOPPED.

Sorry, you're mistaken.
A very old copy of DRIs GEM documentation says:

> WM_TOPPED
> GEM AES uses this message to tell the application that the user has
> requested its window or another applcation's window be moved to the
> top (made active).

(i.e.: the user clicked on one of the application's windows that is NOT
currently on top)

(BTW: I think the "another application's window" part may be obsolete...)

> WM_NEWTOP
> GEM AES uses this message to tell the application that its window has
> just been placed on top (made active)

(...possibly by some external event, like another APP/ACC closing one of its
windows...)

As you can see, these are completely different things; and, unfortunately,
no released Atari GEM version I know of (including the GEM in TOS 3.06) ever
sends WM_NEWTOP!
Many APPs simply use a timer event (500 milliseconds or so) to periodically
check if their window is still on top, wich is (IMHO) a somewhat inelegant
solution (and may cause trouble when the program tries to detect double
clicks).

HeyLo out there!

I've been looking for a decent ANSI emulation accessory to use in the term programs of Freeze Dried Terminal and Interlink.

I once found one for Interlink, but then my Hard Drive crashed, and dummy me did not have a floppy backup.

Freeze Dried Terminal DOES have an ANSI Emulation, but it is not quite TRUE ANSI. (I.E. The colors are off, and you cannot get all the control and escape sequences)

Can someone please point me in the right direction for an Anonymous FTP site where I may find one?

Thanks for any replies!

Okay, from what I can gather from the READMEs in the recent update2?.zoo files from ++jrb and from the docs in the PL 24 MiNT libraries for GCC, the two libraries are very close to the same. However, they're obviously different in some respects, and I'm curious as to whether it's "safe" to use the MiNT libraries with the C++ libraries that are distributed with ++jrb's libs.

Oh, yeah, is there anywhere I can get the source for gcc 2.2.2 (the original distribution) in something like 3MB or less chunks? I've got some space limitations I've got to deal with, and right now it means that I can't get the source down to my ST (not even mentioning the huge modem transfers it would entail).

This is the most STUPID thing I have ever heard of. What do you people
think you are playing with? An Atari 400 or something?

PLEASE, do NOT spread this kind of USELESS information around. If you
need to disassemble the operating system to work out what a memory location
does, then you shouldn't be using it. I doubt the address mentioned
is portable to different TOS versions, let alone TT/STe/Falcon.

There are PLENTY of dumb ways of doing things, but you can at least choose
the portable ones [eg. print 100 linefeeds, then ask where the cursor is :-)].

Atari TT with UNIX developer's kit for sale:

* 16 Meg Fast RAM
* 4 Meg ST RAM
* TTM194 1280x960 monchrome monitor
* TT is mounted in a full size tower case
* 1.44 Meg Floppy
* TOS 3.06
* Migraph Handscanner
* 48 Meg Hard Drive (TOS)
* 212 Meg Hard Drive (UNIX)

TOS Software:

* Calamus
* Calamus SL (with some modules)
* Wordperfect
* Datamanger ST
* LDW Power
* Outline Art
* Touchup
* TOS utilities: Cardfile, Steno/Stalker, Warp-9 etc

UNIX:

* Full developer's kit AT&T SVR4
* X-Window
* Motif
* X-Facemaker
* WiSH Desktop Manager
* GNU developement tools

All original S/W comes with reams of PD S/W on floppys

All licenses for the S/W will be transfered.

PRICE: ALL TIME DEAL FOR OVER $8000.00 of stuff => $3500.00 (US)

Email me if you are interested. Will ship to continental US/Canada

When I provided the address of the variable, I mentioned that (a) it was bad programming practice and (b) it would not be compatable over TOS versions.

However, the user did not ask if it was a good thing to do. He asked how to do it. I also mentioned that a better way (more compatable) would be to use the Line-A variables. Some things cannot be done from certain languages though (like Personal Pascal) so I made another suggestion. The best way to do it, and insure that it would work on any system, would be to place the entire thing in a window and use the INFO line as the status bar. This is slow, though.

I read an advert yesterday claiming that the internal hard disk interface of the new Falcon030 is a IDE standard yet the external drives can run off a SCSI-2 bus. Is this true???

If it is then why do Gasteiner(sp?) and ultimately Atari hope to sell the Falcon with 64Mb HD for 400 pounds more than the machine without HD. One can easily buy a 100+ Mb HD for less than 200 pounds with an IDE interface. Intenal SCSI drives of similar capacity can be bought for less than 300 pounds.

Yes, it is, but there's a catch (as ever!): You need a _lot_ of processing power, and ideally a DSP (Falcon, anyone? :-)). A friend is working on high quality speech synthesis system:

Why don't you just try the curses.arc package available at a.a in directory
/pub/atari/Programming ? It includes a C-Program with various functions to
define and manipulate text windows. Also included is a detailled documentation.

I looked at it and actually found a function for scrolling text upwards in a
specified window. So this might be a solution to your problem. It seems to use
BIOS and XBIOS functions only, so there is a chance it is safe.

Just try it.

> -Andrew

Don't forget the 64M drive is internal: there isn't that much place, so
that the drive is 2"1/2: it's quite a bit more expensive !
And the price difference is also for 4 MB instead of 1M

The price difference may be important, that's true. But what about other
companies ?
NeXT with 16MB is 1000$ more expensive than the same configuration
with 8MB !!
I can find 8MB for about 200$, and put them into the simms sockets myself !

3880. Changing Mouse Forms in MultiTOS

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-14 17:14:48 UTC
From: annius@nanna.research.ptt.nl
Message-ID: <annius.719082888@freyr>
Source record: 42482

Does anybody know how MultiTOS works/should work with mouse forms? When an accessory changes the mouse form and someone elses window is topped by a keyboard command the mouse form isn't reset to an arrow form. This problem only occurs with programs that don't implement rectangle events and are hence only using the arrow and busy bee mouse forms. I think MultiTOS should keep track of the last mouse form set by each application and take care of that. I don't see a way for the program that has just been put on the background to change the mouse back because 1) it doesn't know to what form it should be set and 2) programs don't get a message when a window of another application is topped.

3881. pow() defined in Gnulib?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-14 17:34:58 UTC
From: pbh@pandora.cs.wayne.edu
Message-ID: <1992Oct14.173458.3410@cs.wayne.edu>
Source record: 42480

I just downloaded and installed H. Chu's GCC2.22 for the ST a few days ago. I'm trying to compile a program which uses the pow() function to compute exponents; this function is defined in math.h lib. However, in compiling it tells me _pow is undefined. It pow() there? Do I have to link in any special libs besides the default (crt0?). I ''m also using ftns from stdio.h and stdio.h; no complaints there.

Thanks for any help.

3882. VDI colors: Which ones should one leave alone?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-14 18:33:56 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1992Oct14.183356.123356@rrz.uni-koeln.de>
Source record: 42481

Hi fellow Atarians,

I'm in the process of writing a program that will display color graphics in a window. I'll have to set the VDI colors to suit my needs, as I intend to display a function of two variables by plotting points with lower function values in darker colors -- kinda similar to that standard technique of plotting the Mandelbrot set.
My question is, which of the VDI colors should I leave unchanged? Evidently, if I set all colors from 0 to work_out(13)-1 such that lighter colors have larger numbers, that would suit my need ideally, but it would make it difficult to see windows and the menu, at least if there are 16 or even more colors. Therefore, I figure it would be a good idea to leave some of the VDI colors unchanged, at least colors 0 and 1. Do you think I should leave more colors unchanged?
BTW, how does MultiTOS deal with this? Will the palette always be switched to the one set by the process that owns the active (topmost) window?

Thanx in advance,

Jan

Oddly enough, it doesn't appear that the SCSI connector is accessible from
inside the case, so you can only use IDE for the internal drive. Also, I
don't think you can easily find a 100+ MB IDE drive that is a 2.5" form
factor for the price you're expecting. 3.5", yes, 2.5", not for that price.
I'm still quite perplexed as to why there is an IDE port at all, it would
have been more consistent to jus tuse the SCSI bus both internally and
externally. So it goes.

3884. Event dispatching

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-14 20:09:43 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1992Oct14.200943.131014@rrz.uni-koeln.de>
Source record: 42484

Hi everyone,

in the program I'm currently hacking there will be windows with
different contents. This necessitates two dispatching steps in
event handling, one to branch to the procedure handling the
occurring event, and the second to branch to the procedure
handling the event for the contents of the affected window. The
following chunk of GFA code illustrates the situation:

```
PROCEDURE check_event
SELECT MENU(1)
CASE 10
@menu
CASE 20
@redraw(MENU(4),MENU(5),MENU(6),MENU(7),MENU(8))
CASE 21
.
. (other window events)
.
ENDSELECT
RETURN
'
PROCEDURE redraw(w_handle&,x&,y&,w&,h&)
SELECT @contents(w_handle&) !function contents(w_handle&) returns
' some int describing the contents
' of the window with that handle.
CASE 1
@redraw_contents1(handle&,x&,y&,w&,h&)
CASE 2
@redraw_contents2(handle&,x&,y&,w&,h&)
CASE 3
.
. (other window types)
.
ENDSELECT
RETURN
```

For those unfamiliar with GFA basic, MENU(1) ... MENU(8) contains
the AES message buffer after an AES message event.
The annoyingly unelegant part of this is that the dispatching for
window types must occur for a bunch of other events too
(arrowing, sizing, sliding etc.). Thus, the procedures handling
those other events are all of the same dispatcher type like the
sample redraw() procedure above, in other words, there
necessarily is a considerable amount of redundancy in my code. My

question is, do I overlook a way to avoid this?
Another silly complication is that a bunch of window type
specific reactions to events (e.g. to slider events) necessitate
a complete redrawing of the affected window. To do this, I can
either hack in a procedure redraw_all() like this:

```
PROCEDURE redraw_all(w_handle&)
LOCAL x&,y&,w&,h&
~WIND_GET(w_handle&,11,x&,y&,w&,h&)
WHILE w&>0 or h&>0
@redraw(w_handle&,x&,y&,w&,h&)
~WIND_GET(w_handle&,12,x&,y&,w&,h&)
WEND
RETURN
```

Then, the type of the window will be determined during each call
to the redraw() procedure, which is superfluous as the type is
already known. The only way to avoid this is to write a bunch of
procedures of the type redraw_all_contentsx(), which then call
the corresponding redraw_contentsx() procedures. But that would
mean a bunch of almost identical procedures again.

Thanx for reading through all this stuff,

Jan

I'm having problems running GCC in Gulam in TOSwin. It works perfectly when I run it from Gulam by itself, but in TOSwin, I keep getting:

ld: file not found for TERM=tw52

and it won't compile. It does the same thing for some other programs too, especially when I'm not in the same directory as the program I'm running. I fiddled around with my gulam.g file for a while to no avail. The weird thing is that the very first times I did it it worked. I thought and thought about all the things I changed, but nothing seemed to do with TOSwin. BTW, GCC works from Gulam (without TOSwin) whether or not MiNT is running.

I seem to have lost Eric Smith's e-mail address... does anyone know it offhand? (Eric? :)

Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Hi,

In trying to fix the color in the Ghostscript screen driver, I have come upon the following problem: I want to use the vdi so that the code I write will work on all machines, but Ghostscript wants me to tell it which COLOR REGISTER a given color is in. The problem is that the vdi color indices (which all the vdi routines seem to use) to not correspond to the ST color registers.

Is it possible to use the vdi to either:

1) Set and read the palette using the value of the COLOR REGISTER and NOT the vdi color index?

2) Use the vdi to find the mapping between color registers and vdi color indices?

3) Get around this some other way?

For 2 and 4 bit color on a regular ST, I can just set up an array which maps color registers to color indices, but I think that this is not practical for larger palettes (especially since I don't know what the mapping is for the TT and Falcon modes).

Please do not send me information about XBIOS calls, since I am insisting on using the vdi. My GEM documentation is incomplete, and says nothing about any functions to manipulate the color.

Thanks,

-Tim Gallivan

Try compiling with -lpml on the end. The function is actually in the
Portable Math Library. In general, this is the place to look for floating
point functions.

From: Hayo_Schmidt@hh.maus.de
Message-ID: <A8364@HH.maus.de>
Source record: 42385

Hello world, hello Eric!

I am just writing on a TSR, that manipulates the VDI/AES, Gemdos and Bios trap.

Since i am using always Setexc, i found out the hard way, that if you start a TSR before MiNT, the AES/VDI bypass an the BIOS bypass (i presume) are still working. But i didn't catch the GEMDOS trap anymore. Under MiNT, the Malloc never knocked on my door. OK, the way out is quite simple, start the TSR by MiNT and everything seems to be alright.

But there is still one sincere problem: the Traps are Setexc'ed on runtime, but the GEM tends to throw out the AES trap routine whenever it wants to annoy us (f.e. after starting TOS or TTP's). To get back into the trap, i use Setexc. This _must_ be done in the Bios trap, while waiting for Setexc 257. But my program is already terminated, so who is made responsible for this Setexc by MiNT and which problems do i cause. Is there a way out, a daemon process is obviously none.

Greetings,
Hayo Schmidt
from Hamburg

Gday
On the subject of TSR's malloc'ing memory - can hardware interrupt exceptions in supervisor mode also malloc memory ?.. I'm trying to get a exception routine working that calls a Lattice 5.06.01 malloc call (in the library, but gets bus errors half way through...).. Should I be calling gemdos directly via a trap ?

And - also is it safe to use IPL7 for hardware interrupts ?? - or should I use IPL5 (I'm using an Atari MEGA ST)

Thanks
Kym

>Torgny.Lindberg@eua.ericsson.se

For one thing Please get a copy of AHDI 3.1, your version is very badly stuffed ans should be never used...

If your STE has this IC C025913-38, then you have the bad DMA chip, 40 pin chip under the disk drive..

The good IC is C398739-001A, also the AHDI 3.0 can cause the same kind of problems..

The New replacment IC C398739-001A is free, but there could be a charge in fitting it ..

I'd say at least 16. That'll give you 0 colours on an ST(E)! That should be
enough :) But really, we should hear a TT owner about this.

>BTW, how does MultiTOS deal with this? Will the palette always be
>switched to the one set by the process that owns the active

That's what I am hoping as well, and there are a lot more things that
should be relative to a process. Let's hope they'll think of these things in
the very first version, and avoid a phenomenon similar to TOS 1.4, which made
all the previous TOSes kind of rediculous. (Call it MultiTOS 1.4 :)

Does anyone actually know what the difference between the SM144 and the new SM146 monitors are ?

I'll probabley phone up some mail order place and ask them before buying one, in the end, as no mags seem to have discovered the existance of the SM146 yet !!! (What do you expect, when the only thing they can think of at the moment is Falcon , falcon, and FALCON :-)

Thanks in advance...

Your description fits the symptons of the faulty DMA-ICs in the STE exactly.
A friend of mine had the same problems and after changing the IC everything
was fine.

3895. Trouble with templates in GNU C++

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-15 10:23:15 UTC
From: subiaagb@w350zrz.zrz.tu-berlin.de
Message-ID: <CMY7YZP@mailgzrz.tu-berlin.de>
Source record: 42341

Hi C++ users,

I have to implement a generic list class within a class library.
Therefore I want to use templates instead of deriving from on
base class. But my gcc (2.2.2 PL3) does not seem to work correct with it.

I wrote a little test program (template.cc):

```
// BEGIN //

template<class T> class A
{
private:
T a;
public:
A( T aa ): a(aa) {}

T Get( void );
};

int main( void )
{
A<int> a1(2):

return a1.Get();
}

template<class T> T A<T>::Get( void )
{
return a;
}

// END //
```

The compiler works fine, but the linker aborts with a message like:

```
template.o: A<int>::Get - symbol not found ( or the like )
```

But, if I put the definition of Get directly below the class A
declaration, it works. I want to know: Is it a problem of the C++
language or the compiler or the linker (which is PL31)?

Another question is:
In the infos about libg++ I found a description of generic list,
stack and queue classes, but my g++.olb doesn't contain such things.
Is it impossible to implement it with G++?

Thanks.

Use C - make a structure that contains pointers to all the functions
necessary for window-handling and swap pointers depending on the
current window. Then write *one* generic window-handling function.
Piece of cake... in C :-)
Sorry, just couldn't resist...

> off and then redraw it).
Using the delete line and insert line vt52 commands lets you put a status line(s) anywhere on the screen without too much trouble. For example, to scroll the screen up without moving the status line, insert a line above the status (scrolling it down in the process) then scroll the screen up and redraw the blank line.

> Even better is to put your program into
> a GEM window and manage the VT52 emulation yourself, but obviously
> that's a lot more work.

Yes, this is what I'm in the process of doing for one of my programs. I've so far got round to having all of the screen output run through a single printf() like routine, so now it should be relatively simple to switch that from Bios to Gem, once I've written some code to handle the vt52 escape stuff in a window. Far easier than going through several 100k of code changing everything manually.

> most of us use Uniterm right? That's all I want. When information is
> coming in over the modem I want it to scroll up at line 20 instead of line
> 23.

OK, how about the following bit of code (not guaranteed to work, since its off the top of my head, but it should give you the basics). ScreenLines is a variable containing the number of lines on screen, input_line is the line you've just got from the modem. I've split the printf()s into multiple calls to make commenting easier - do them all as one really:

This is for a two line (Emacs-like) status line.

```
---------
/* save cursor position (if necessary) */
printf("\033j");
/* Position cursor at bottom of screen */
printf("\033Y%c ",ScreenLines-1+32);
/* Scroll the screen up */
printf("\n");
/* Position cursor at start of status line */
printf("\033Y%c ",ScreenLines-3+32);
/* Insert a blank line (is this the right code??) */
printf("\033L");
/* Print your input line - make sure it doesn't have a
newline character in it beforehand */
printf("%s",input_line);
/* restore cursor position (again, if necessary) */
printf("\033k");

---------
```

Wrap all this up in a nice little routine, and bob's your uncle. In fact, make it a #define, since it simplifies to a single line of code.

Is that any help?

Kev

3899. bad luck/sectors

From: stigvi@solan.unit.no
Message-ID: <1992Oct15.121329.4685@ugle.unit.no>
Source record: 42344

I have a problem with an external hard-disk
for my TT which I hope someone can help me with.
Some days ago I borrowed a longer cable for it so I could
put the noisy thing out of my way. I also did a format with HDX
on the disk. Because of noise in the cable, HDX registered several
thousands of bad sectors. The BIG problem is that when I reformat
with the old cable, HDX lists all these `bad` sectors as
previously found bad sectors and the disk is still nearly unusable:-(
Does someone know how to delete this list of bad sectors? Please....

As far as I know, IDE drives are not that cheaper than SCSI ones.
I can't believe the difference is significant enough to cover the extra cost
of developing the IDE internal interface !

Sorry, not true. Monitor Master only allows you to switch between an
Atari monochrome (SM124, etc.) and an Atari color (SC1224, etc) monitor.
It has no provisions for mulitsync connections.

For mulitsyncs, you need the Omniswitch, the IB Multisync switchbox, or
the switcher made by Omnimon Peripherals (I can't remember the name),
depending on your connection requirements.

Your code works fine with Comeau C++ 3.0 With Templates.
Further, I am not aware of any strange scoping rules or anything that
should prohibit this. OTOH compilers are using differing mechanisms
to address ATI (automatic template instantiation) and hence you may
be caught in a g++ idiosyncrasy on this although it could equally be a bug.
Perhaps it might change things as well to make A(T aa) an out of line
generic description as you have done with Get rather than in in-line?

Well, I have a 6m additional cable between my Mega ST2 (with blitter) and
the monitor. It works quite fine, except that the focus is a bit worse.

I have a cable with 7 wires which are shielded INDIVIDUALLY. This may cause
the difference: cables with a single shielding only give bad results, i.e.
the phenomena you have described.

So the problem may be located with your cable.

My local electronics dealer states that even a 20m cable should work fine.

Sincerely,
Thomas.

Source record: 42356

Well this is an interesting question. If you are writing programs
for an ST with TOS 1.4 or less , or STe, not MegaSTe, with its original
ROMs then avoid colors 0, and 1. With the newer versions of TOS you
can define any color to be used for any individual part of a window.

So use any colour you want just make sure you restore the color.

There should be no problems. jrb's code is very clean, and I've tried
to keep the mntlib code similarly clean. The differences are mostly
confined to the lowest level Unix emulation functions (e.g. open(),
read(), write()) and even there the interfaces are the same, it's just
that they do things differently. (For example, mntlib implements symbolic
links by calling the appropriate MiNT functions, gcclib does it with
UNIXMODE.)

>mapping is for the TT and Falcon modes).

ST Magazine (if I remember well) proposed to get the mapping by executing
v_trnfm() on a small raster that contains one pixel of each colour.
Unfortunately, because of speed, v_trnfm() is not an appropriate function when
using color modes (bit planes are seperated). The mapping itself is probably
some un-re-traceable combination of a couple of shifts and adds or sth. (Or is
it a table somewhere in the ROM? Atari why are you doing this to us?)

Anyway the number of colours in false-color modes (forgive the term) will
probably not exceed 256 so you'll be fine with a 256 pixel raster. What I mean
is that the 16 bit modes are mostly 5:5:6 rgb coded so this whole hassle
is irrelevant. A table for 65536 24 bit colours would get a bit big.

Could it be cost of the drives? Are 2.5" IDE drives less expensive for the consumer than 2.5" SCSI drives (if there are any around)? Perhaps Atari wanted to provide an inexpensive hard drive solution for the Falcon and IDE was it.

Firstly, I made a mistake, but it has nothing to do with the problem:

<=== : the line should be really `A<int> a1(2);' (sorry, it is not
the real program)

It seems to me, it is a bug (or something else) of either the GNU compiler
or the linker. ( An earlier version of G++ (2.1) gave the same results )
I tried these lines on a Sparc with G++ 2.2.2, and got this message:

ld: Undefined symbol
_Get__t1A1Zi
```

After, I made A(T aa) non-inline, and got the same messages.
Then I put both non-inline functions directly after the class declaration,
and IT WORKED?

Is there somebody in this group who had the same problems with templates
and G++? Or do I have simply to turn on a compiler or linker switch?
Until a resolution is found, I have to write all the list code in one
file List.h, which will be included by other modules, then all works
correct, except that I have to wait a very long time for every compilation.

Thanks for contributions!

3912. Help with date setting on ICD AdSCSI+ host adapter

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-15 17:19:36 UTC
From: snoret@egon.unx.sas.com
Message-ID: <Bw6Aso.95B@unx.sas.com>
Source record: 42355

I purchased an ICD AdSCSI+ host adapter at WAACE to replace my old Supra. The problem is, the date setting doesn't work. I have successfully set the time, and can set the date, but it always reverts back to something like 11/14/28, or 11/12/20. I originally thought it only returned to this type of value after a reboot, but last night I set the date, then did a few things (like log into GEnie for about 1/2 hour), then checked the date. It had reset by itself!

I have a 1040STf, 1meg, and TOS 1.0 (ugh! but I've got 1.4 on order!).

Has anyone else had a similar problem? I have all the latest revs of the ICD software. (The date on the host adapter is Sept. 92!)

Thanks in advance!

Rick

>declaration, it works. I want to know: Is it a problem of the C++
>language or the compiler or the linker (which is PL31)?

I understand this is correct behaviour. You have to specify the
function before using it, in at least one compilational unit.

But note that ARM specifies this to be implementation defined...

>Another question is:
>In the infos about libg++ I found a description of generic list,
>stack and queue classes, but my g++.olb doesn't contain such things.
>Is it impossible to implement it with G++?

It is possible. You should use the genclass program.
Oops! genclass is a /bin/sh script. Get a /bin/sh compatible shell
(bash will do, if you have the memory -- haven't tried it!), and
use genclass.

As usual, talking about the Sun version of gcc, as i don't have enough
memory on my ST to run g++ :-(.

I think the real reason is the form factor. The 1040STe case is too
small for a 3-1/2 inch mechanism. Only a 2.5 inch drive could fit
comfortably. So what did Atari do?

Well, there are tons of 2.5 inch drives available from the IBM world.
They were being used in all those laptops. Unfortunately, they were
mostly IDE drives. Well, it turns out that Atari had already designed
an IDE interface for the STBook. Why not use it on the Falcon too?

An added advantage of using an IDE drive is the low power comsumption.
Since these drives are being used in laptops, they probably comsume
much less power than a typical SCSI drive.

3916. Handscanners etc

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-16 02:17:12 UTC
From: dennis@citr.uq.oz.au
Message-ID: <dennis.719201832@citr.uq.oz.au>
Source record: 42361
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Greetings,

Question: Are the various scanners available for the Atari ST hardware specific, or can one suitable for an Amiga be used with the correct software?

The reason is, I see many handscanners and so forth for sale in the local trading post, but they are advertised as suitable for Amiga'a. I'd like to purchase one of these if they can be used with little or no modification as they are very reasonable priced.

If the answer is yes, is Touch-Up suitable software...

All answers appreciated...

3917. STE Blitter Concern

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-16 05:34:58 UTC
From: glens@natinst.com
Message-ID: <1bmnf2INNl33@falcon.natinst.com>
Source record: 42379

What happens if an interrupt occurs during a large blit when using
the BLiTTER in HOG mode? I have not experienced any problems yet but my
concern is that I have a critical VBI installed that must run before the
first scan line is fetched. I am using the BLiTTER in HOG mode and am doing
very large blits. I hope that an interrupt stops the blitter and allows the
68000 to service the interrupt but I am worried that the interrupt is held
off until the end of the blit.

Thanks for any help.

How did you make it non-inline? With a compiler switch?

>Then I put both non-inline functions directly after the class declaration,
>and IT WORKED?

That is what I mentioned above. Still doesn't help in deducing whether
this is a bug of feature of g++ templates though.

>Is there somebody in this group who had the same problems with templates
>and G++? Or do I have simply to turn on a compiler or linker switch?

Another guess (as I've more than an incling about how templates work)
but a switch will most likely not do the trick for this.

>Until a resolution is found, I have to write all the list code in one
>file List.h, which will be included by other modules, then all works
>correct, except that I have to wait a very long time for every compilation.

That's a reasonable approach anyway in many cases. Of course with
Comeau C++ we have a repository system available with most of our ports
and hence all does not always need to be recompiled just to please the
template class/function generation mechanism.

Besides normal scoping/overloading/etc issues for things like prototypes,
there is currently no additional constraint like this that I know of.
Where do you find this mentioned in the ARM?

>But note that ARM specifies this to be implementation defined...

Actually as I recall it is unspecified. Anyway, hence, you don't need
to specify the definition before using it. It just becomes part of
"normal" resolution.

|> the library, but gets bus errors half way through...).. Should I be
|> calling gemdos directly via a trap ?
|>

Memory management routines, whether is TOS or in libc usually modify global
data structures (free lists etc) which makes them non-reenterant - ie you
can't safely call them from interrupts. When I needed a malloc/free that
was callable both from interrupt code & normal code I ended up writing my
own in asm.

|> And - also is it safe to use IPL7 for hardware interrupts ?? -
|> or should I use IPL5 (I'm using an Atari MEGA ST)

You can set IPL to want you want providing:

If you access hardware registers/TOS variables you want it high enough
so that you don't get interrupted by a TOS routine using the same registers/
variables. The classic example is the Yamaha sound chip - you need to
be at IPL 7 to ensure the selectedregister number doesn't change between you
setting it & writing to the selected register.

Your interrupt code must not have the IPL too high for too long so that
other high priority interrupt don't run on time. At IPL 7 nothing else runs
and the MIDI port can overrun in 320uS so stick to below 300uS (Atari themselves
screwed up here - they actually recommend a 1mS limit).
At IPL 5 all the MFP stuff can interrupt you* but VBI stuff is blocked so stick
below about 10mS and you should be OK.

*Assuming your routine isn't MFP OR the MFP interrupt is higher priority than
yours OR you've cleared your interrupt-in-service bit on the MFP chip.

So now I have to ask the question, does the Falcon040 have an internal IDE interface and will it take the cheaper 3.5" drives???

I think I'll probably be better to buy an external SCSI-2 for the extra money and faster access times than mess around trying to find a 2.5" IDE drive of 100Mb capacity!

An internal 64Mb IDE drive can just sod off for that price, the falcon isn't a laptop portable thingy. A slightly bigger case and cheaper HD expansion would have made my day.

Hrrummmphhh!

I'm sure you get the gist of my disappointment.

Or you can make one yourself. The biggest problem is to get that
din-plug to fit Atari's monitor socket. I must say mine does
not work perfectly as there is some ghosting in b/w mode and
I do not know what is the problem (bad cable, the switch or something
to do with impedance, as I just connected the monochrome out to
R/G/B-lines).

But it is quite handy as I have also Matrix C32 graphics card,
so I can switch between all resolutions.

>I have a cable with 7 wires which are shielded INDIVIDUALLY. This may cause
>the difference: cables with a single shielding only give bad results, i.e.
>the phenomena you have described.

Screening is vital but so is impedance. Your video signal is sent along a
transmission line but, while the distances are short, you may be able to
get away with just about any wire. The longer the distance, the more essential
it is to use the right cable. The wrong cable will slow down the transitions
and so you will lose detail in the image. Not only that, you can get reflections
from the joins which will cause ghosts a short distance from the real image.

The right cable is 75 ohm co-ax, as long as atari have kept to the standard.
There is a type especially made for video (RG159 I think, but don't hold me
to it as I don't have the references here).

3927. Division of file into resource/data

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-16 12:52:23 UTC
From: annius@sif.research.ptt.nl
Message-ID: <annius.719239943@freyr>
Source record: 42376

In comp.editors there is a discussion going about the misery around different tab sizes. Some people prefer 3, some prefer 8 and how do you determine what the person who wrote a text used when he was typing the text?

In this discussion a Macintosh fanatic mentioned that there was no problem about this on the Mac, for Macs files are always devided into a resource part and an actual body of data. It is clear that this kind of file structure has enormous advantages to offer.

Now I heard that MiNT is in certain conditions capable of handling file names of maximum 15 characters and no restriction to the number of dots in the filename, or what characters out of 256 you use. This gave me the following idea:

With each file in 8:3 format we associate a resource file, like this:

abcdefgh.ijk data file

.abcdefgh.ijkrc resource file

The resource files will be hidden for old TOS programs and won't be shown in directories unless you ask for them to be shown (the hidden flag is set, for example.) If you copy files, future shells will take care of copying the resource files as well. Some extra support could be given by MiNT.

As to the definition of the resource files, I would suggest a chunk file format (e.g. IFF and MID files). Something like

TRSC `Tos Resource File' chunk
<length of file, long word>

<any chain of chunks that start with>
<four byte chunk identifier>
<length of chunk, long word>

So we could for example implement a TABS chunk that defines a number of tab stops.

(- what do you think? -)

There's one thing I forgot to mention in my article about the data/resource partitioning of files:

Apart from the TABS example a FOLD chunk for use with folding text editors could be defined. Another idea is a NOTE chunk with a small clarifying text about the file (cf. Amiga and Mac).

Actually, the procedure check_event() which I outlined in my
original posting is almost exactly the generic window-handling
function you suggest. I don't see why it should make any
difference whether one branches to the appropriate function by
swapping pointers or by a SELECT-CASE construct. The number of
structures containing pointers can't be smaller than the number
of SELECT @contents(w_handle&) constructs.
The difference I see between your suggestion and my program is
that you're dispatching for the window type first, then for the
AES window event. So, would you say it's better to do things this
way round? I always have thought the sequence of dispatching
steps I chose is better because one has to dispatch for all
window events in any case, but some window events (such as
WM_FULLED) don't necessitate full dispatching for window types.

To be honest, I've never handled a situation like this before, but
following my 'intuition' I would do the following (and I don't know
if any of this can be implemented in C - and I also don't know if
this is the best way to handle things, so all flames to dev/null
please).
I would first make structures, containing pointers to all the window-
handling functions. One structure per window-type - or (better) one
structure per window. You now have e.g. win_struct1, win_struct2, etc.
(or you could put them in an array). Now declare a pointer to this
kind of window-structs, e.g.
win_struct *curr_window;
The dispatch loop would then be something like

```
handle_event(int window_handle, int event)
{ switch (window_handle)
{ case wh1: /* let curr_window opint to the */
curr_window=win_struct1; /* structure corresponding to */
break; /* the current window */
case wh2:
curr_window=win_struct2;
break
etcetera.....
}

switch(event)
{ case window_sized: /* call the appropriate structure- */
curr_window->sizefunc; /* member (which is a function) */
break;
```

```
case window_moved:
curr_window->movefunc;
break;
etcetera...
}
}
```

The syntax for calling functions is different from the above, but it's just to get the idea... (can't get the syntax for this kind of stuff in my head for some reason :).

Anyway, this way you need only two switches... Of course some function pointers could be empty e.g. when a particular window is not sizeable you'll have no 'sizefunc' for that window - but that's no problem as you'll never receive a 'size event' for that window, so it doesn't matter where the curr_window->sizefunc points to. You might (just to be safe) put dummy functions in unused slots.
But as I said, I don't know if anything remotely similar can be done in GFA.

Of course you could also do everything the other way around - make structs that contain all the sizefuncs, movefuncs, etc. etc - a structure member per window (instead of per event as I suggested). The first switch will now switch on event and let the pointer point to the right-kind-of-action-structure. The second switch will then select the right member from this structure=the right window. I find it however not too intuitive to do it this way - I prefer my solution :).

Hope this is of any help...
BTW, this is just a 'wild idea' - I've never treid it, but can't see why it wouldn't work....

I've done this by including a (100 msec) timer event in my main program's message handling loop. It does a bunch of things, including checking who owns the spot in the center of the screen (that isn't exactly legit, but all the ACCs I was worried about at the time ALWAYS appeared there on open).

Once I detect an 'accessory active' state, I check a search grid instead of one spot, and wait for the intruder to go away. This is probably even less legit, but maybe it'll get you started.

The difference might not be large, but there certainly are a difference.
Another reason to go for IDE just came to my mind: availability! The
2.5" IDE drives are used in most notebook computers, and i do not
know of any using 2.5" SCSI drives.

>I can't believe the difference is significant enough to cover the extra cost
>of developing the IDE internal interface !

Well, the IDE interface was developed for the ST-Book, so it was no extra cost
in the Falcon project i guess. I've not seen the schematics of the Falcon and
the ST-Book, but the IDE interface is probably only a extra PAL working
together with the blitterchip. After all IDE isn't that a complex buss.

I beleive the vdi color mapping just moves the black from 2 to
whatever the top number of colours is, and shifts the other colours
down accordingly. I don't have access to the TT notes to see if this is
onsistant throught the tt video modes though.

No kind of interrupt routine should ever try to make a GEMDOS system
call (including Malloc), because GEMDOS is not re-entrant. Since most
library malloc() calls eventaully call the GEMDOS Malloc(), this
means you'll have to roll your own memory allocation (probably by
allocating a big chunk of memory before your program installs itself
as a TSR, and managing that memory yourself).

3936. Modula2 on the Atari ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-16 22:01:21 UTC
From: mrt7455@evtprp0b
Message-ID: <373@evtprp0b.UUCP>
Source record: 42392
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech,comp.lang.modula2

What is the status of Modula-2 on the Atari ST platform? It is my impression that Jefferson Software support has died. Ana-systems implementation was mostly just-to-see-if-we-could-do-it. I know that TDI died tho I thought I heard that the source for their libraries was available. FST had an implementation of the language on the ST but after I sent them money for the upgrade that was supposed to coincide with the MS-DOS FST version 2 upgrade, I NEVER heard from them. Modula-2 is a reasonable nice language to work in. Did Jeferson Software ever release the version they were trying to get working on the Atari Minix environment? I remember them saying that it was real close before Jefferson kinda died.

Stay far, far away from the Talon Omniswitch. Others have had luck with it, but I haven't.

The IB Computers Multi-Switch is good.

Omnimon Peripherals is no longer in business or is no longer supporting the ST. This is according to Neil Weinress on GEnie who worked with them. They produced the OmniX3 multisync switchbox as well as a 1.44meg floppy modification for the ST.

Toad Computers in Maryland has multisync switchboxes, as well as ATY Computers in Oakland, CA who custom builds them, made-to-order. Both companies advertise in ST magazines.

I've had similar problems, and though I had eliminated them. First,
on someone on GEnie's advice, I'd turned off recognition of all scsi
id's except 0 and 1 on my booter. Unfortunately, I didn't realise that
this cut access to the clock. I turned id 6 back on, and using the new
booter that reads the clock, i had no problems until yesterday, when my
clock got nuked for the first time in a while. Coincidently, I also used
Aladdin for the first time in several months. I'm going to do some tests
now to see if it's the culpret. Thanks for pointing out the possible
problem. From your manual. you must know you have to run icdtime to
actually set the ICD clock, the booter and timeset programs are read
only, as far as I know.

Well this could be some help to you all, the Atari puts out some
1 volt pk-pk video signal, this can overload some monitors (gives ghosts)
that can only take some 0.75 volts, so fit small 22 ohm resistors in the
monitor plug, must be at monitor end, one for each colour..

If you are having problem getting the monitor connectors, we have plenty here
at $2.95nz.

NOTE: Sony also make this monitor connector.

Part No. is 1-560-946-00 PLUG (WITH lOCK) 13P

> obviously none.

Just as in normal TOS, the Setexc will take place in the context of whatever
program made the system call that your TSR intercepted. In most cases this
won't make much difference. There are a few vectors (the process
termination vector and the critical error vector, for example) which are
per-process, but most vectors (including the trap #2 vector) are global.

You mentioned that your program would work if installed before MiNT,
except that GEMDOS Malloc calls would then not be received by your TSR.
I should warn you that all of the internal workings of Malloc are completely
different under MiNT than they were under "normal" TOS, so if your program
relies on TOS's Malloc operating a certain way then there could be trouble!

pow() is defined in pml.olb (the Portable Math Library) - just like on Unix,
you need to use the "-lm" option to use the maths library (except you use
"-lpml").

To find out what is defined (and not defined) in a library, use "nm.ttp",
which should be with the other GCC binaries.

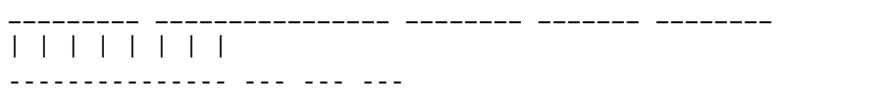
3947. Question: Multi-Syncs with ST or Falcon

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-17 17:28:24 UTC
From: wmagro@uiuc.edu
Message-ID: <BwA0JD.Ayr@news.cso.uiuc.edu>
Source record: 42396

I had some difficulty setting up my Taxan MultiVision 770+ with my ST. First my 1040STf did not output a composite sync, which was required by my monitor when in analog mode (and is the VGA standard, i believe). I observed that the separate horizontal and vertical sync lines go _low_ to signal a sync and built a small AND circuit and put it where the rf modulator would be in my ST. I output the composite negative-going sync on pin 12 of the monitor connector and all is well (except for all the ghosting recently discussed. I haven't yet tried r. sheppard's suggestion of 22 ohm resistors on the _monitor_ end).

When I got my hands on a falcon, I tried to plug my ST-cabled multisync into the ST monitor connector without success. So now I've begun to wonder: did I get the composite sync correct on my ST. Could someone who knows please tell me whether the composite sync an ST generates look like:

Vblank hreturn hreturn hreturn



(what my multisync accepts) or like this:

? Perhaps, it could be that the falcon doesn't spit out a composite sync when the ST monitor block is attached, but I can't see why not. I did a continuity test, and the Falcon's composite sync line _is_ connected to the usual ST composite sync pin (12 i think). Unfortunately, I didn't have a scope to look at the line.

Thanks in advance,

Bill Magro

ARGH. Never malloc memeory unless you are the current GEMDOS process.
Why? Simply because TOS always mallocs the space for the last program called
with exec(). If you malloc() some, and the current program terminates, your
memory will get deallocated automatically, and you wouldn't know it.
Which means terrible effects could happen if let's say, GEM decides to
get some itself for a huge .rsc file, and you decide to write to it !!!

TSR's should rely exclusively on what they start with.

Patrick.

Quick Question here. I am the author of the Kickoff 2 Team Editor,
and in teh program my resource editor (MKRSC, the PD program) crashed if I
tried to make more than 7 objects. Does anyone know of another PD resource
editor or do I have to forkout for WERCS?
Secondly, in the program I had a lot of trouble with the window output.
Originally, I set up an object whic I placed in a window, updateing text into
it. Now, I have changed to printing to the screen using the v_gtext command.
Although this is slower, it does save memory (important if your programming
in sozobon C on a 520ST!). Is there a GEM protocol telling me which method to
use?

>Bill Magro

Well to get a true Composite sunc I used a xor/xnor, it is posible to use the
+ 12v via 1.5 k, that comes out of pin 8 of the monitor connector to drive
the I.C., but this is only fitted to later machines..

Most sync's are negative going, but buy using a xnor it should be posible to
change it...

I've been having major problems running GCC in TOSwin. I've been using Gulam, which works fine outside TOSwin, but not inside it. I've finally convinced myself to try another shell. I donwloaded several, all of which seem to crash. Does ANYONE out there successfully compile with GCC from a shell in TOSwin? I would really like to hear how it's done! If possible, I'd like to see your shell's configuration file (i.e. gulam.g or tcsh.rc). I've been banging my head for a week trying to get it to work, but to no avail. Thanks in advance...

All true and good advice, but it's worse than that.

You should never call GEMDOS from an interrupt because GEMDOS is not re-entrant. This means that it cannot support two processes calling it at once.

Imagine if the main application is in the middle of some GEMDOS call when your hardware interrupt comes along. Control is passed to your handler, which calls GEMDOS... bang.

The gasteiner advert does seem to have a slight cock up. They are pricing a
1meg + internal 64meg drive machine at 899 pounds - the same machine with 4
meg costs a lot more. On the more appealing side, they are selling 2, 4, 8
and 16 meg versions with and without drive, and the 4 meg version is quite
nicely priced (579 pounds, I think).

I guess this either has to go into the FAQ, or somebody has to fix the termcap code in Emacs ... that's at least the sixth time I'm answering this question:

Emacs uses binary I/O to access the termcap file, and it assumes that lines end with LF, not CR/LF as on the ST. Remove all CRs from you termcap file and it should work.

Perhaps it's just that your system runs out of memory and the crash has nothing to do with the shell you're running?

GCC grabs all memory it can get by default, so you'd probably like to run your make under limit.ttp.

I have 4 megs, in a TT/030. Maybe that's still not enough... but I'm just compiling hello.c. The error Gulam gives me is "ld: file not found for TERM=tw52" or if I change the terminal type it says "ld: file not found for LINES=30". If I make a file called "TERM=tw5" it says it's an invalid input file. GCC-LD seems to think that my terminal variables are files it's supposed to use! It works fine without TOSwin, even if a copy of gulam is loaded into TOSwin when I run Gulam by itself. So I don't think it's a memory problem. Do you run GCC from a shell in TOSwin? Have you ever had such problems? Maybe I need a later version of GCC-LD. It wasn't in the "GCC201B02.ZOO" on atari.archive. Which file should I download to get the latest GCC-LD?

Thanks,

Dan Aylward

Source record: 42410

My Megafile 30 is misbehaving. Starting a few days ago, both LED blink with about 3 or 4 Hz after power-on before normal spin-up of the disk sets on after 1 or 2 seconds. That reminds me of a failure I had with the same disk three years, and where the power supply had to be replaced in the end. Nowadays, I wouldn't spend that amount of money again for this slow device, but if somebody has a tip on what to check (in the power supply ?) I would try to fix it myself.

Thanks in advance for any help.

3962. Undeleting a File - Is It Possible?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-19 19:07:22 UTC
From: thom@agora.rain.com
Message-ID: <BwDuGB.H0x@agora.rain.com>
Source record: 42413

Late one night, after working for many hours at my ST, I accidentally deleted the file I was working on. There is no back-up. I've lost twelve solid hours of editing that I couldn't possibly recreate - it was a lengthy composition for piano.
As a software engineer, I know that it is possible, at least in principle, to undelete a file (e.g., on the IBM PC). Is there a PD program somewhere - perhaps someone could forward it? - which has been in use a fair amount of time that could undelete this file?
Any information would be appreciated. Thanks.

Thom

3963. Minix File System, how reliable is it?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-20 02:44:56 UTC
From: sjkinneb@mtu.edu
Message-ID: <1992Oct20.024456.10283@mtu.edu>
Source record: 42414

I got MFS055 from atari.archive and one of the readme files states that I shouldn't use it unless I have FSCK from Minix. I understand the problems that TOS would ordinarily have with the different file system. I have played around with it some, but I have been wary of commiting myself to setting up MINT permanently using MFS on a partition on my hard drive. If anyone with experience with MFS could offer any suggestions, it would be appreciated.

Also, are there any decent hard drive backup utilities that are compatible with the minix file system?

Thank you in advance.

sjkinneb@mtu.edu

3964. RS-232 Buffer

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-20 06:50:54 UTC
From: alexd@milton.u.washington.edu
Message-ID: <1992Oct20.065054.19515@u.washington.edu>
Source record: 42415

An inexperienced (C) programmer (myself) would like to know how to change the address of the RS-232 Buffer.

The values of the RS-232 buffer are contained and returned in the Iorec() function.

```
- struct iorec
{
*buffer location char *io_buf;
*buffer size char io_bufsiz;
char io_head;
char io_tail;
char io_low;'
char io_high;
}
```

I am able to change the buffer size.

```
- int *bufrec;
bufrec = Iorec();
*(bufrec + 2) = 10000;
```

However I cannot seem to use malloc() to change the buffer location of iorec (changing the first element of the struct iorec to the address allocated by malloc() (char *io_buf;))

It was suggested that I should change the size and location of the buffer in order to fix a problem that I have had plague me for over a month.
*The problem - I have a peripheral device that sends hex packets back. The device sends back most packets properly but one packet (longer than most) doesnt always get through the RS-232 without losing some information.
The theory is that the head of the index gets past the tail because the size of the circular buffer is too small especially if the data is coming in at a high rate.

If anyone out there can help me out . I would greatly appreciate it.

Thanks

I've been using it for about a year now and have had no problems at all
(even now I have recompiled it without the auto sync()ing after each write).
Stephen Henson has written a version of fsck for MiNT.. but this is
definitely an alpha release.

>

I use Gnu Tar's incremental backup features. (Note: I had to recompile Gnu
Tar with Unix options using the MiNT libs to get it to work)

3966. MiNT-related questions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-20 08:13:31 UTC
From: sbp@jet.uk
Message-ID: <1992Oct20.081331.18217@jet.uk>
Source record: 42417

I have a couple of MiNT-related questions which someone might be able to help me with:

1) Running TOSWIN under MiNT 0.95, I have seen that if I run ksh in a window and execute a command like

```
echo "anything FRED\0" >>u:/pipe/tosrun
```

I can get a new window to open with the title "FRED". Unfortunately the window is immediately marked as "exited".

Is there a way to append a "message" to /pipe/tosrun asking it to open a window and run something inside ?

2) In moving from MiNT 0.94 to 0.95, the timestamp on files in u:/proc has changed its meaning (it now shows the date & time at which the process was started instead of the amount of CPU the process has consumed).

Does anyone know how, given a process filename, I can find out how much CPU time that process has used ?

Thanks in advance for any help.

OK!

Let's hope it's implemented the right way! If there are a lot more of these
nice surprises in 4.0, I'll see myself writing ST-incompatible software within
a year, though.

Try putting the line 'unsetenv ARGV' at the beginning of your gulam.g
file, *or* turning the ARGV= passing mechanism off in TOSWIN (using the
'Environment...' menu selection). Gulam will use ARGV when launching
a program, but it seems to get very confused if ARGV is used for gulam.prg
itself (it leaves the ARGV= string hanging in the environment, so that
subsequent programs get environment variables passed to them as arguments).

Try
echo -n "directory program arguments\0" >>u:/pipe/tosrun

e.g.: to run the program c:\bin\ls.ttp in directory c:\etc, with arguments
'-l', you would do:

echo -n "c:\etc c:\bin\ls.ttp -l\0" >>u:/pipe/tosrun

> Does anyone know how, given a process filename, I can find
> out how much CPU time that process has used ?

You open the process's entry in u:\proc, and read the data from
the PROC structure. One of the things in there is the amount of user
and system time used by the process (in milliseconds, although it's
accurate only to ~5 milliseconds). See the source code for the "ps"
utility (in mntutl95.zoo) for more details.

3971. mint&tcsh curser leaves blocks behind

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-20 14:02:59 UTC
From: selick@csa.bu.edu
Message-ID: <99077@bu.edu>
Source record: 42422

Has anybody else had this problem? I switched to v0.95 mint a while back, and suddenly the curser is leaving blocks wherever you hit a return. It also has a tendency to erase characters when you backspace over them and just do some unattractive things.

Thanks for the help,
Steve

On a subject which no-one seems to have mentioned yet, but which is a bit of a problem, what happens to all our old Atari hard drives (I have a Protar 50DC) when the Falcon is released. Can we get a convertor cable of some sort to allow us to plug an old style Atari HD into the Falcons SCSI2 port, or do we have to invalidate our guarantees by opening the case & disconnecting the SCSI driver boards in the HD ?
This could make upgrading an expensive option, so any comments appreciated....

Er is een bit in de conterm-variabele die je kunt zetten waarna Bconin in het hoogste woord altijd een scancode geeft. (Je kunt hier niet zomaar vanuit gaan.) Dan moet je de scancodes van de cursortoetsen weten. Tip: ze zitten allemaal rond de 70/80. (Check even in een boek)

In response to this, I re-post this article from the honourable Eric Smith :-

==========

No problem -- TOSWIN opens up a pipe (u:\pipe\tosrun) and listens there
for requests. To run a program in a TOSRUN window, you just have to write
the initial directory for the program, program name, and arguments, all
separated by spaces and terminated by a 0. (Make sure that all of this is
written with one Fwrite call, since otherwise if two programs are accessing
the pipe at the same time their writes could be interleaved.)

Here's a sample implementation:
---------- cut here ----------
```
/*
* runtos: a small program that will launch a TOS or TTP program
* in a TOSWIN window.
* To compile:
* gcc -O -mshort -o runtos.prg runtos.c -lgem16
* To run:
* runtos someprog.tos arg1 arg2 arg3
* OR
* Using the desktop, do an "Install Application" on runtos.prg.
* For "document type", use .TOS. Now, double clicking on a TOS
* program will automatically start it up in a TOSWIN window.
* (unfortunately, it will also cause all TOSWIN windows to be
* hidden -- you'll have to select "TOS programs" from the DESK
* menu to get them back again).
```

```
* BUGS
* See above. Also, it would be nice to have a "runttp.prg"
* that would prompt for .TTP arguments. This is left as an
* exercise for the interested reader. Reporting errors is
* also left as an exercise.
*
* "runtos" was written by Eric R. Smith and is hereby placed in
* the public domain.
*/

#include <minimal.h>

long _stksize = 2*1024;

int
main(int argc, char **argv)
{
/* BUG: shouldn't have a fixed size buffer */
static char buf[1024];
char *where = buf;
int i, fd;
long r;

if (!argv[1]) return 2;

/* first, put the path */
*where++ = Dgetdrv() + 'A';
*where++ = ':';
Dgetpath(where, 0);
if (!*where) *where = '\\';
strcat(where, " ");

/* next, put the program */
strcat(where, argv[1]);

/* finally, put the arguments */
for (i = 2; argv[i]; i++) {
strcat(where, " ");
strcat(where, argv[i]);
}

fd = Fopen("U:\\PIPE\\TOSRUN", 2);
if (fd < 0) return 1;

r = strlen(buf) + 1;

if (Fwrite(fd, r, buf) != r)
return 1;

return 0;
}

================================================================================
```

3977. MiNT KSH and environment variables

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-20 17:43:31 UTC
From: mal5781@tamuts.tamu.edu
Message-ID: <1992Oct20.174331.27144@tamsun.tamu.edu>
Source record: 42425

I once again attempted to convert to MiNT. I am happy with MiNT 0.95 but
I need some advice.

What do I need to do in KSH (under MiNT) to get TOS programs to read the
variables. I am tryin to use "elvis" and no matter what I set the
"TMP" variable to, elvis complains that is connot creat a temporary
file. When I use "ls" I only get the "ls" to give me the top
level directory for the drive. I am forced to write:

ls $(pwd)

of I want to see my current directory.

Should I abandon my old friend the Korn Shell and go back to buggy gulam or
try to convert to BASH?

Also, is TOSWIN hostile to Universal Item Selector III? I can't get TOSWIN
to execute with a bus error when I have the UIS III accesory under the
desktop accessory window.

Thanks.

You don't mention which version of TOS you're running, but it's
possible that the 'fasttext' driver doesn't like your version of
TOS. Try commenting out the
CON=u:\dev\fasttext
line in your mint.cnf file by putting a '#' character at the beginning
of that line.

I have FINALLY :) gotten an acceptable MiNT/toswin setup achieved on my system... still using mintshel, but compiling with GCC 2.1 in a toswin is not so bad if you can do other things while that is happening.
Anyways, I have a MegaSTe 2.06/4 megs...however it seems that Warp 9's new extendosave feature is incompatible with mint or more specifically Toswin. Any ideas on which progs fault this may be? Anyone get these to mutually work? Also, I can't seem to run quickindex under mint at all... is this also a known incompatibility?
Neither of these are enough to make me put MINT away, but just curious if anyone has any ideas on these problems.

>try to convert to BASH?

I think ASH should work ok. (The /bin/sh clone). You could move to tcsh, which definitely is MiNT friendly (and relatively TOS friendly, to boot. Major bonus...) I'm a csh family aficionado, so I'm a little biased here.

The problem that you're having with elvis is that it is hardcoded somewhere to look for the /tmp directory. It won't look at the TMP variable; I've run into this with combinations of TOS/MiNT in both tcsh and mupfel.

A solution that will work under either TOS or MiNT is to make sure that you have a directory /tmp at the top level on EACH partition.

Under MiNT, you can do a symbolic link so that /tmp goes to some arbitrary place, say /dev/f/tmp. This only works with MiNT though. I'd rather go with the /tmp on each partition...

I don't know what can be done about the ls problem... It must be failing to read the current path out of the environment variable, but I don't know why. I've used ksh without having this problem; are you sure it isn't ls that's broken?

>Also, is TOSWIN hostile to Universal Item Selector III? I can't get TOSWIN
>to execute with a bus error when I have the UIS III accesory under the
>desktop accessory window.

I use UIS III and haven't had any MiNT crashes that were at all related to UIS; I run the UIS Desk Acc. under MultiDesk and haven't had any problems with doing it that way.

Your directory is minimally altered just after deleting a file -- only the
first letter of the file is changed to a special character. However, only
the head of the linked list of clusters making up the file is in this
directory entry. The head of the linked list goes to the file allocation
table to obtain each next cluster of the file.

Unfortunately, the file allocation table's linked list of clusters for the
file has been freed up again, and I don't believe that you can recover it.

> {
> *buffer location char *io_buf;
> *buffer size char io_bufsiz;
> char io_head;
> char io_tail;
> char io_low;'
> char io_high;
> }

Off the top of my head, forgive(or correct) any mistakes.

declare a global *buff_pointr /* if you're going to save the old io_rec */

unsigned int siz_of_new_buffer; /* assuming int is 2 bytes
otherwise, you'll need to
declare the vaue in 2 chars */

if (buff_pointr= (malloc(size_of_new_buffer))){
io__buf = buff_pointr;
io_bufsize = size_of_new_buffer_wanted;
io_head = io_tail = io_buf; /* I think the head and tail */
/* out in the same position */
Also, you'll have to set the high and low pointers.
Not sure where they initially point. If you plan to deinstall
this without a reboot, save the original pointers.

First of all, Falcon's TOS contains AES 3.3, which is different from
MultiTOS' AES. Furthermore, the new AES will not send WM_NEWTOP, but
WM_ONTOP (which has a different message number).

3993. ls in tcsh on u drive doesn't work

Yes, try running Mupfel under MiNT (whether console or full screen). It has to
do with the choice for a console device (in mint.cnf set con=fastterm or sth).
This solves the cursor on/off thing but not the redirection of Bios functions
(Consbfix doesn't seem to work). See my article on comp.sys.atari.st.

4000. Problems with (old) ICD Advantage SCSI host adapter ...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-21 18:14:12 UTC
From: mbaffoni@skat.usc.edu
Message-ID: <1c46lkINNk20@skat.usc.edu>
Source record: 42295

Hi,

I am having problems with an old (circa 1989) ICD host adapter (with
built-in clock) on my TT. Before I start, I should say that it was working
a couple of days ago so it is not a compatibility problem.

OK. Well, I was going to give my cousin the 48MB drive that came with
my TT (its a Seagate 157N-1 that I replaced with a Q105LPS). So I took my
Q80s off of the host adapter (which had been working fine) and connected
the Seagate to the host adapter. The Seagate was terminated, as was my 80s.
When I tried to load the ICD boot software (I normally boot with AHDI5.0)
it could not find a host adapter. When I ran IDcheck, it would not find the
drive at ACSI0, and it would "skip" over ACSI6 (where the clock is located).
I found through experimentation that I could get IDcheck to see the clock
if I a) took off the terminating resistors of the drive (still no drive tho),
or b) completely removed the SCSI cable from the drive. Then I tried it with
my Q80s - same problem. Thinking that I blew my drives, I checked them using
the internal scsi of the TT - I found that although I couldn't get the Seagate
to be recognized, there was nothing wrong with the 80s.
Just to make sure it wasn't the cable, I used another known good 50
pin SCSI cable and had the same problems.

So what I need to know is a) did I miss a trick? b) if the host adapter
is dead, what is the cheapest ICD host adapter (preferably with clock and can
be mounted in an external drive chasis, again preferably mountable in an IBM XT
case)? c) Would anyone happen to have either the logic board from a 157N-1
that is good (but the disks are bad) that they would be willing to sell me,
or the number of a company that could repair/sell me a new 157N-1 logic board.

Oh, something I was thinking about. I don't have a second ACSI cable
to check this out, but could the ACSI cable be damaged so that it can give
valid data for the internal clock but not for the drive? Also, another
symptom I almost forgot was that when the drive was connected to the host
adapter (and IDcheck could not see the ICD clock), when I exited the program,
all accesses to the floppy result in a "the data on floppy may be damaged"
error, but as soon as I disconnect the drive, it works fine.

Thanks to anyone who can shed some light here.

-Mike Baffoni

>
>Unfortunately, the file allocation table's linked list of clusters for the
>file has been freed up again, and I don't believe that you can recover it.

Yes you can. With some work, of course, but it can be done. It's even easy
if it's a text file, because you can just look at all the unused clusters,
and link them all up in the FAT (File Allocation Table). I've done it many
times (OK, It's not too bright to delete so many files :-), and I always
got the whole thing back.
Using a program like DLII (Mentionned previously on this thread) sure eases
the whole thing, so get it from a.a.

Patrick.

>--

When you exec() a .TOS or .TTP program (Or double-click on the destop),
GEM gets turned off. That means no windows, menus, dialog boxes, etc ...
and no mouse either. But the program gets a nice clear screen to start
with.
.PRG or .APP programs run under GEM. Although they can use everything
.TOS or .TTP programs can (text), they get the advantage of being able to
use GEM stuff.
The major difference is that the desktop will never give the command line
dialog for GEM programs. Instead, files written as applications for the
program (In the Install Application submenu) will call the it when
double-clicked on, and will send their filename and path as command line.
Otherwise, it's just to tell the user what to expect: .PRG or .APP tells
the user that he'll get fancy windows and menus. .TOS means he gets bogged
down text only stuff (boring ...)

Patrick.

>other, then why was the 'other' made?
> Doesn't even sem that long since the TT came out...Hmmm.

The Falcon is a quite different from the TT. The TT has a more bussineslike
aproach, in that it has a expasionslot, can have much more memory installed
(I have seen cards with up to 256MB on), it takes a larger internal harddisk,
it has a 1280*960 resolution suitable for DTP and professional wordprocessing
etc. It is also quite expensive, but offers more 'traditional' cpu-power than
the falcon.

The falcon is a dedicated multi-media machine with resolutions perfect for
video applications, and CD quality sound with direct-to-disk recording
capabilities. Just read the specs given in one of the FAQ's to see how
different these machines are!

> Doesn't even sem that long since the TT came out...Hmmm.

The TT is more appropriate for desktop publishing and CAD work while the
Falcon is more in tune (pun?) with music, multimedia, and animation. The TT
has a detachable keyboard and the Falcon does not (yet). The Falcon has some
advanced features, such as SCSI-2 and DSP, which will no doubt be included with
a machine that will eventually replace the TT.

> Also, you'll have to set the high and low pointers.
>Not sure where they initially point. If you plan to deinstall
>this without a reboot, save the original pointers.

The high and low water marks are not pointers. They are amounts: when the amount of data in the receive buffer is greater than the high water mark, the system will send ^S (assuming XON/XOFF flow control) to the remote host. When it has processed enough of the buffer so that the amount of data in the receive buffer is less than the low water mark, it sends ^Q to the host. A good high water mark is about 75% to 85% of the size of your buffer; a value around 100 should always do for low water mark (unless of course you're setting a really small buffer.)

Also note that for he RS-232 device, Iorec() returns a pointer to TWO iorec structures, the first for the receive buffer, and the second for the transmit buffer. (the pointer you get is to the first structure, and the second structure immediately follows it in memory.)

Cheers,
entropy

>Toswin. Any ideas on which progs fault this may be? Anyone get these to
>mutually work? Also, I can't seem to run quickindex under mint at all... is
>this also a known incompatibility?

I've had this problem as well, the screen saver has been prone to locking up
my system. Don't know yet where the problem is, but I'd guess that Warp 9's
VBlank interrupt handler is doing something naughty. The MiNT handler saves
and restores registers before it does anything, and doesn't make any OS calls,
so I doubt that it is the cause of the problem. Also, I couldn't get Warp 9
to work with MiNT at all when using the Warp 9 control panel. Seems to be a
bit of contention in grabbing the system trap vectors. QuickIndex 2.2 locks
up on me in the text output tests when BIOS buffering is on, but works OK
with it off. (But of course, text output is godawful slow when buffering is
off.) Uniterm also exits with a bus error when executing an auto-login macro
if BIOS buffering is on. I have no idea why these programs are affected in
this manner, since it looks like the buffering code is perfectly good.

> Neither of these are enough to make me put MINT away, but just curious
>if anyone has any ideas on these problems.

Right now I wish I had a decent 68000 simulator. I've been trying to track
down a bug I introduced into my copy's context-switch code for the past
couple weeks, with no luck. (It's awfully strange to run a debugger, put
a breakpoint into kernel code, and watch the kernel keep on executing while
the breakpoint gets triggered! I'm like "goddamit, I want *everything* to
stop now, cut it out!!!")

It all depends on the settings in desktop.inf (or newdesk.inf). Normally
all program files with extensions PRG and APP are started with
mouse on and the standard background. Files with extensions TOS and
TTP get a blank screen, no mouse and a text cursor.

BTW: actually, GEM applications really should have the APP extension --
this is a very good method to prevent people from copying them into
the AUTO folder.

Hello !
I have an Atari-Mega-ST 2 with 4MB and TOS 1.2 .
Since some weeks I use MiNT 0.95 and TCSH as programming environment for
gcc 2.1.
But there are some little problems.
1.) When I start mint.prg from directory tcsh the tcsh.rc will not be reed
and then I have no alias and no environment-variables given in tcsh.rc .
2.) It isn't posssible to make a clear screen. What do I need to have the
vt52 terminal and to use the ESC-sequence's ?
3.) I also will use Perl sometimes and I want to run some perlskript.
What do I have to do, running such a perlskript from the command-line
under TOS 1.2 . (The same problem I have using my Scheme-Interpreter)
Do I need a better TOS ???

If there is someone who can help me, you can senfd me a mail or answer it
in this news-group. Thanks ....

Quite possibly. I might give them a ring in the next few days and see. It would also be interesting to know if their 4 meg configuration leaves space on the board to go further yourself.

4015. tr for MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-22 11:07:40 UTC
From: neuhaus@bloch.informatik.uni-kl.de
Message-ID: <neuhaus.719752060@bloch>
Source record: 42307

I am posting this for a friend of mine who cannot post by himself. He can send out and receive email through <hhemker@informatik.uni-kl.de>.

This posting was mildly edited by me <neuhaus@informatik.uni-kl.de>.

---

tr for atari-st

If you don't know what tr is -- leave it alone, you won't need it!

This version of tr works with MiNT (0.94 and probably higher), but should work with TOS as well (didn't test that, though).

Readme for tr - Oct 1992 distribution

This is a version of tr written from scratch only by looking at the manpage (SunOS 4.xx). It was surprisingly easy to code.

So I suppose there are some *FEATURES* which should not be supported (;->). I call this version 01 (much room to fix bugs in versions 02 to 09).

tr was written using GCC-atari-st-V1.40 PL2 with MiNT-libs PL19 and has been tested under MiNT 0.94. Everything seems to work well (to me).

I included getopt.h (which is part of many FSF software distributions), in case it's not in your /gnu/include (or wherever you keep your header files). The prototype for the getopt function can be found in unistd.h, but not the global variables that are needed.

Please mail bug reports to hhemker@informatik.uni-kl.de.
If you're not able to use email, try paper mail. The address is

Heiner Hemker
Koenigstrasse 34
D-6750 Kaiserslautern
germany

If you make copies of tr, please read the copyright notice in the file COPYING (right, the FSF standard).

Have fun
Heiner

---

tr can be obtained through ftp.uni-kl.de:pub/atari/mint, in the
files tr-bin.zoo and tr-src.zoo. Some documentation is in tr.txt.

Have fun.

>Can someone tell me why there is a Falcon 030_and_ the TT030? What's wrong
>witht the TT? Why is the Falcon necessary? If one is actually better than the
>other, then why was the 'other' made?

The TT is the high-powered big-brother of the ST/STe series. The Falcon,
on the other hand, is the low-end of the "next generation" of Ataris,
though it does keep compatibility with the old series, newer software
will be written to use the specific design enhancements of the Falcon
(such as the DSP, the multitude of new graphics modes, etc). Most likely
a higher end of the Falcon030 will probably use a 040 chip...

The TT, in general, is a more powerful system (faster, more memory,
a higher graphics mode). But the TT does not have some of the Falcon's
enhancements. With the present software available, the TT would be
a definite choice. But when Falcon-specific software becomes available
(multi-media stuff in particular) then there'll be a different
set of uses for the Falcon than probably any of the ST/TT series could
do quite as well.

Message-ID: <1992Oct22.143336.8495@bnr.ca>
Source record: 42311

The TT vs Falcon is a very good question. The Falcon is targeted at the home entertainment(read multi-media) market. The machines actually are very similar in price, when comparably equipped. The TT processor does run at 32Mhz, vs 16Mhz, this only helps when both the instruction and data caches are enabled, and/or you have what is called TT-Ram.

The TT does make a much better workstation, because of it's speed and seperate keyboard. One very nice feature of the TT is the 3U-VME card slot. You can purchase a network card, a video card, extra serial lines and plug any one board into the TT. While more than one card slot, and a 6U card size would be more to my preference the TT is much more easily expanable than the Falcon.

The TT also comes with the FPU, floating point unit, while the Falcon comes with the DSP. Both have their advantages, but I would definitely get an FPU added to a Falcon, the socket is supposedly in there.

Right now my choice is the TT, because it is available. It is price competitive with comparably equipped 386 DX systems.

Hi net.world,

I have this possibly foolish question: Is there a function or command in GFA basic that is equivalent to the ftell() function in C, i.e. that can be used to determine the current position in an open file? Unfortunately, I could neither find such a thing in the GFA manuals nor can I use the GEMDOS FSEEK() function, because I don't know how to determine the GEMDOS file handle associated with a GFA file channel #.

Any ideas? Other than using C or C++ anyway, please :-)

Sounds like you either plugged the cable in upside down (not likely if it
was a keyed connector) or both the drive and the host adapter were trying
to supply TERMPWR. Many drives have a jumper that lets you enable or disable
supplying power to the terminating resistors. If there is no such jumper,
you need to clip the conductor on that pin at the end of the cable that
connects to the drive. I don't think you can disable TERMPWR from the ICD
host adapter end. In either case, (cable upside down, or too many sources
of TERMPWR) it sounds like the Seagate controller board is toast.

Very puzzling.

I've received mail from people who have the same model of computer as myself (1040 STFM) who ARE running PCDitto 3.01.

My PCDitto 3.01 refuses to run, it starts up, asks for DOS disk, reads the dos disk and then dies.

Is it possible that my 1.2 tos roms are not the same as other 1.2 roms?

Or are there other hardware components that vary slightly depending on where my machine was assembled?

Heck, I designed two memory upgrade boards for the ST. They both took hours to make. I never did use them though, and I can't remember why.

Let me tell you, if you ever want to make a memory upgrade board. DON'T use point to point wiring, etch a circuit board!!

SO I have these two .5 Meg or 2 Meg boards laying around somewhere. They electrically checked out OK.

I think it is a lot easier to piggyback the chips. I have done that a few times. All you need are some good docs. I might just post some on to the net.

4029. SC1224 & Sega Genesis?

Message-ID: <c523sB2w165w@bluemoon.rn.com>
Source record: 42323

HeyLo out there!

I have a question that I hope SOMEone out there can help me with.

I have a SupraDrive 30 that fails after booting.

It will boot fine, and I can load applications with it for a while, but after about 1 1/2 to 2 hours of use, it sounds like the heads die down, and then I get error messages stating that I need to check the drive and make sure that the cables are correctly attached.

If I shut the drive down and wait about 3-5 minutes, I can turn it back on and take off where I got the error message. This is really anoying when I am d/loading large files from the internet.

Can anyone give me an idea of what to check first? And if the case itself is still good, but the drive is going bad, then what could I use in place of it? I have been thinking about checking into upgrading it anyway.

Thanks for any replys!

Source record: 42327

I need some straight fact, not rumors, tales, or heresay. What is an 8 or 16MHz 68000 faster than, concerning the Intel 80x86 chips? How fast is a 68030 compared to a 386DX-33 or 40MHz system? And my last question...

Does a 50MHz 68030 truely exist? FAST Technologies say they have a 50MHz version of the TT upgrade for Atari Mega ST's (not STe's). I found this to be quite amazing, to say the least. I know they did a "speed hack" on a 16MHz 68000 to bring it up to 25Mhz, but I sure hope the 50MHz 68030 isn't one of those. I like stock power, not "trick enhanced" power, though, there may be no real difference 'tween the two.

Please make all replies in Email to: jared@midiline.la.ca.us

DLII isn't a good solution. I've used it and got corrupted data. Not only
my files where corrupted, it also corrupted my FATs. So I can't recommend
DLII.

Try to get CHKDISK3. It's from Atari. They only ditribute it to registered
developers, but I saw the programm on a few FTP-servers. That would be the
best solution (IMHO).

4037. MMU/RAM upgrade trouble

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-23 14:22:40 UTC
From: lynbech@daimi.aau.dk
Message-ID: <1992Oct23.142240.5815@daimi.aau.dk>
Source record: 42207

I have recently installed a homebrewed RAM upgrade in my 1040 STFM of ancient vintage (1987 I think).

My problem is that I haven't got any contact to the upper 3MB. One possible and likely cause of this would be that address line A9, which is not original connected, is bogus.

I know that some early MMU's could not address more than 1MB, but according to ST Format, where I got the information, my MMU has got the good serial number.

Before I rush out and spend lots of money on a new MMU chip, I would like to hear if anybody else has any problems of this sort. It is not just a configuration problem? Could it have something to do with resistance/capacitance/noise problems (connection is just a wire from the socket to the RAM board)?

Source record: 42192

>what's the difference between the SM144 monitor and the SM146?

I've used a 124, 125 & 146. They all have a clear picture. I don't like the 124 as much as much the 125 and 146, which are very nice (because of the stands & the adjustability).

When I was trying to buy a new monitor recently I was told that around 50% of 144s suffer from distortion in one corner and so the 144 is being discontinued and replaced by the 146. I have never seen a 144, so I have no idea if this is true, or how bad the distortion is, but I have no reason to disbelieve it - the company I was phoning lost a sale by warning me.

4039. Compressing .PRG and/or .TOS, .TTP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-23 15:39:09 UTC
From: erkamp@JANUS.ARC.AB.CA
Message-ID: <1992Oct23.093910.47@mimas.arc.ab.ca>

I am looking for a good program that will compress .PRG files and/or .TTP and .TOS files while still allowing them to run. So far the only program I have found is 'Pack_Ice v2.4'. Are there others that are better? Any help would be appreciated as my Hard Drive is full.

Bob

4040. Best RS232 fix?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-23 16:05:07 UTC
From: neuhaus@vier.informatik.uni-kl.de
Message-ID: <neuhaus.719856307@vier>
Source record: 42197

Hello.

I would like to use my Atari (1040 STF, 4MB memory, TOS 1.4) as a
terminal for a larger computer that I bought recently. Now I know
that there are still bugs in TOS 1.4, concerning RTS/CTS flow control
handling, and probably the serial port interface in general.

My question is:

What is the best RS232 fix for the ST so far?

`Best' in this case means

a. fixes all known bugs (especially the RTS/CTS bug),
b. is freeware or shareware (no crippleware!),
c. runs out of the box (no compilation necessary), and
d. Runs from the AUTO folder, installs itself and
terminates. I want to be able to use the fix with
terminal programs.

Memory requirements are not an issue.

Please reply by email, since I don't read this newsgroup very often.

If you reply, please send mail to neuhaus@informatik.uni-kl.de, not
neuhaus@vier.informatik.uni-kl.de. This is a bug in our news software,
and I'm not sure when we'll get it fixed. Thank you.

The TT has a 32Mhz 68030 as opposed to the Falcon's 16Mhz 68030. The TT also comes with a 68882 math coprocessor; the Falcon has a socket for one.

>> Falcon is more in tune (pun?) with music, multimedia, and animation. The TT
>
>Then the Falcon has more/better graphics/sound? Why? An how much different?
>

The TT has 6 possible stock resolutions. The Falcon has 32 possible stock resolutions. ("Stock" = "out of the box".) The TT has the STE's 8-bit audio; the Falcon has 16-bit audio.

>> has a detachable keyboard and the Falcon does not (yet). The Falcon has some
>> advanced features, such as SCSI-2 and DSP, which will no doubt be included
> ^^^^^^^^^^^^^^
>What are/What is the point of these features?

SCSI-2 is an advanced version of the SCSI interface, used to attach external devices such as hard drives and othe storage media, as well as scanners and other peripherals.

DSP is a "digital signal processor," which does just that: processes digital signals. :^) There's better, more extensive descriptions of it available.

I think every major ST magazine in the US has covered the Falcon to a decent degree. If you don't read at least one regularly, you should.

Just one word of warning. As I recall DLII works pretty well with files located in the root of a file system, but if you try to undelete a file in a folder, it writes the data back offset by 1 (sector, cluster?) which can create far worse problems that you started with. Including, of course, not retrieving the file you originally wanted.

I trashed a big chunk of at least one drive this way, a couple years ago, and it took a lot of work to recover things (with tools other than DLII).

> question...

An 8MHz ST is almost dead-even with a 12MHz '286. Floating point math
will be faster on the AT, unless you're using GFA Basic. Then the ST is
faster at FP (barely). I haven't tested a 16MHz ST against anything, but
I'd suspect it's about the same as a 20MHz '286 (not quite double the
speed of an 8MHz, thanks to the bus and lots of other things), or about
the same as a 16MHz '386sx.

A 32MHz 68030 Mac is at roughly the same speed as a 33MHz 386dx. I
know the TT is a bit slower at some things, maybe 25MHz 386dx equivalent.
I have no idea about the 68040 or the 486.

Hope this helps...

If you're willing to spend $25 or so, the DC Utilities comes with a program
called "DC Squish" which apparently does just what you mentioned,
compressing your programs while still allowing you to run them as they were
before. The packages also comes with DC Extract, a GEM-based archiver which
does ARC, LZH, ZIP, and ZOO.

4046. screen flicker from TT ram

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-23 23:14:31 UTC
From: ens@ccu.umanitoba.ca
Message-ID: <1992Oct23.231431.28069@ccu.umanitoba.ca>
Source record: 42202
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I get a very irritating screen flicker (or interference of some kind) whenever the TT ram is accessed. Some programs (like Stalker) are difficult to look at because the interference is present all the time. During bootup, the screen only flickers when tt ram is being tested.

I have a TT with tos 3.06 and 32 Meg TT ram on a GE Soft Mighty Mic expansion board. The inside of the tt is mostly free of the usual shielding found on ST's and an earlier TT that I saw, although the plastic moulding appears to be painted with some kind of conductive paint. There is a metal box around the power supply and a half-cover over what i assume is the source of the rf monitor signal.

Has anyone else had similar trouble and if so is there a way to stop it with strategically placed foil? I tried just covering the memory with foil but that didn't help.

Suggestions welcome.

How old is "old" ? If it is really an old drive, is the warranty still going to be in effect anyway?

I would imagine that it would be pretty easy to make the right adapter cable, but it would also probably be even easier simply to remove the ACSI -> SCSI adapter card, since the drive itself is most likely to be SCSI based, or an ST506 drive with an Adaptec SCSI controller.

>power, though, there may be no real difference 'tween the two.

The difference is reliability; Motorola tests their parts at various speeds and assigns speed ratings based on where the parts begin to fail. In the case of the 68000, however, maybe Motorola just doesn't see a market for fast 68000s and so doesn't bother rating them beyond 16MHz. Those chips certainly are reliable at 20, not too sure about 25.

>not fit for purpose hence the supplier **must** repair/replace/refund at his
>own expense.

Well they did offer to repair it free, but the cost of sending it in,
and being without my machine for 3 weeks put me off. The reason for the 3 week
delay was, they said, that a technician was leaving (sad really). The reason
for the 10ukp charge was that when they were doing them free , the system was
being abused. The honest punter has to pay again :-(
As it turned out, the problem wasn't with the DMA chip after all, but
was an over-heating PSU. i only realise this when i got a new Quantum and
put it in with the other drive. Installing a fan cured it (fingers X'ed)

Forget about the chips. Just use SIMMs. It's cheaper and easier to
use (a lot of work is already done (for example the capacitors)).

You can make you board with some veroboard (no need to 'design and
burn' (with UV or whatever) you board. It's quite straightforward
and easy as soon as you're not afraid of a solder iron !
(the most difficult part for me was to find docs on pinouts
(especially for the Simms)

> - Mark Hughes (Caves of Steel 509-624-2078) mhughes@comtch.spk.wa.us

Don't forget the 386sx is generally slower running DOS-prg than 286
(cause of internal splitting of memory accesses).
A 68030 is slightly faster than a 386dx.
The same holds for 68040 relative to 486 (espescially for floating
point unit: 68040 is almost twice as fast)
A 68030 at 50Mhz does exist officially, as does a 33Mhz 68040

Anyway, all those speed are very 'environement' dependent: whether
there is a cache (whether it is good or not) or not and other
things (bus speed etc..) can change dramatically the results
(and the prg themselves can influence the results (whether they are
well-optimized for that precise processor or not, ...))

The 68060 is expected to be about as fast as the 'pentium' P5
(and the 6800 is still slower than the 68000)

Stefan

4052. Page flipping flicker fix anyone?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-24 05:21:50 UTC
From: wilsont@rahul.net
Message-ID: <BwM1KE.31n@rahul.net>
Source record: 42201

While writing a 3D app, i used two pages of memory so you can't see
the screen being drawn.
At any rate, according to various docs, it says i do a Setscreen followed
by a Vsync. well. i get a flicker halfway down the screen.
its consistant, unlike when i leave it out (then the flicker is really bad)

whats the solution?

thanks!
(please don't say ASM!!!)

This sounds like the usual rubish from untrustworthy dealers..

Here the SM144 is sold for ST,STE, Mega STE as it has a SPEAKER fitted,
the TT has its own speaker so does not need a monitor with a speaker,
its that simple...

I have found 2 articles on SIMM/SIP upgrades both are good but have a few
things left out like the resistor for the ninth address bit of the ram (33ohm)
also no mention of connecting both 5 volts and 0 volt lines, and disabling
the ninth data bit, it must not be left disconnected (only for 9 bit SIMMS),
and no mention of pinouts for the MMU..

Also I have found that you can place the 2 megs as the first or second bank
with out any problem..

The only problems in using plug in SIMMS is in getting the sockets, I do have a
updated version of the SIMM upgrade, none plug in, E-Mail me and I will try and
mail it to you....

I have upgraded some 5 machines with the SIMMS stuck down, on ST/STFM's
and Megas also my machine does have plug in SIMMS, I did manage to get some
sample SIMM sockets from Molex, I uses a small piece of
Vero Board (Matrix Board) and its mounted between the PSU and Disk drive,
on top of the metal sceen case..

I was a computer Eng for some 40 years but now work for a TV/Video repair shop,
so I hope I can help some otheres here...

4055. How many sectors?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-24 23:01:15 UTC
From: dsb@duke.cs.duke.edu
Message-ID: <719967674@macbeth.cs.duke.edu>
Source record: 42208

Okay, spot me here. The BIOS (or GEMDOS or whoever's responsible for this) in older (<1.04?) versions of TOS used a signed 16-bit integer to index hard disk sectors, allowing ~32,000 sectors per partition; recent versions use an unsigned 16-bit integer, allowing ~65,000 sectors per partition. With TOS 2.06, then, I should be able to format my 52MB hard drive into a single partition using ~52,000 1K sectors. I just tried it with AHDI 5.00 and it used 2K sectors.

Apparently AHDI doesn't recognize that my system can handle more sectors per partition; is there any way of informing it of this? Failing that, is there a way to muck about with the boot sector directly and trick it into using smaller sectors? [I just finished formatting the disk, so it's not like my data's at risk ;)].

On a related note, the documentation for the Minix .XFS for MiNT alludes to an "extended" Rwabs() syscall that uses a 32-bit int to index sectors, and that AHDI 5.00 groks this call. Is there a way to use this call to set the partition up with ~100,000 512-byte sectors?

[Why am I bothering? Well, as a developer/hacker, I expect to have lots of <2K files laying around, and I'd rather not waste the space.]

Thanks, as always.

I currently own an atari 1040 st with 1 meg on board, but
only gives me 512k out of 1 mego n power up. Is there any type of memory test
program that I can run to see which chips are bad on the 1040 st motherboard
?

Any help will be appreciated.

If you have not used the disk after deleting the file, use
DLII024.ARC to undelete the file. I have always been succeful
in recovering files with this utility.
It should be on atari.archive.umich.edu under Diskutils or
something similar.
One time I did a program mistake and deleted an entire directory
of irreplaceble source code and was able to recover every file :-)

Carlos Varela.

>it's not like my data's at risk ;)].

It's no big deal to alter the disk to what you want. Sector 0 of the disk
contains the BPB (Bios Partition Block), and it can be altered with a
normal diskeditor.
Here's what you do!

The word starting at Byte $0b (11) tells how many bytes/sector:
In your case 00 08 ($0800 = 2048 bytes) Remember that words have their low
byte first on the DISK!! Alter this to 00 04 ($0400 = 1024bytes).

The word starting at byte $13 (19) tells how many clusters there are on the disk
Read the number and double it. REMEMBER that the FIRST byte is the LOW byte
(i.e. if it reads "12 34", the value is actually $3412)!!

The byte at $16 (22) tells how many sectors/FAT. Quadruple this figure (only
relevant if you'r using the disk with TOS filesystem)!

This should do the trick, but it works only on drives smaller than 64MB!!
I did this trick today myself on a 62MB partition intended for the Minix
filesystem extention for MiNT!

I guess it's pointless to discuss features of unfinished AES versions
(I shouldn't have replied in the first place). The 'current' state
of MultiTOS is described in the developer documentation and in the
Falcon book published by 'Data Becker'. New versions of AES will
have new features, and everybody who's really developing GEM applications
should be developer and MultiTOS tester anyway.

>this is a very good method to prevent people from copying them into
>the AUTO folder.

Indeed, it would be a good idea to officially distinguish THREE types of
program statuses: TOS/GEM and AUTO. So:

TOS/TTP: blank screen, text cursor, no mouse (although, I suppose in
MultiTOS nobody will actually still use the built-
in VT52 emulator if it's still full screen; you
can always install your favourite `xterm' as an
application for TOS/TTP extensions)
PRG: blank screen, nothing at all (but anything possible)
APP/GTP: desktop and mouse

Actually I wonder if the comment after TOS/TTP doesn't change things for all of
the three categories...

From: s.smith01@ic.ac.uk
Message-ID: <9210261023.AA20069@cscmgb.cc.ic.ac.uk>
Source record: 42215

Does anyone know the appropriate type of joysticks for the STe's
analog joystick ports (the new 15-pin ones).

What voltages does the A/D run between? (0-5v) (0-1v) (+/-5) ?
Is it linear (I hope so) ?

I have several applications that may benefit from any analog stick and
any information would be very useful.

Also, just out of interest, how *fast* are those A/D's ? Are they fast enough
for Data Logging (probably) or maybe even sound sampling (doubt it)?

Thanks In Advance,

Howie

4064. Scrolling graphics (fast!)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-26 10:31:55 UTC
From: s.smith01@ic.ac.uk
Message-ID: <9210261031.AA20348@cscmgb.cc.ic.ac.uk>
Source record: 42216

This is probably some sort of trade secret, but ...

How do I scroll an area of the screen fast?

I have a screen layout of tiled graphics (16*16 blocks) in a window of
10*10 tiles (actually two windows side by side). The window is onto a
larger (say, 128*128 tiles) area of data - not graphics data, but tile
numbers (I don't have that sort of memory!). I need to be able to
display a chunk of this area to the nearest pixel i.e. smooth-scroll
across the area.

How is this done? I tried a few ways mostly variation on using sprites for
each block, and drawing them all one-by-one. Obviously there is a fundamental
improvement to be made here. Is there an easy(ish) way of implementing this?

The sort of speed I am thinking of is like Supercars or Magic Pockets,
although it needn't necessarily be *smooth*.
I have a fairly large 'palette' of tiles, which seems to preclude
pre-shifting (IMHO).

Any help would be much appreciated

Having just gone through a traumatic nightmare of a DIY upgrade I would like to thorw in some advise too.

First: do as the instruction says. DO NOT CUT _ANY_ CORNERS. For instance, do use sockets, even though the may be expensive and hard to get. You'll save blood, sweat and tears.

Second: find somewhere to put the expansion, and be sure to _CHECK_ that it fits. Do not rely on your eye measurement, and do all this BEFORE you start cutting up the wires.

Last: Try to get your hands on a volt-meter/continuity tester. It makes troubleshooting much easier.

I found an instruction on a.a. describing a SIPP upgrade, but it is easily converted into a SIMM upgrade, and I think that it works. My problems are mostly selfinflicted.

Hi all,
I have a problem compiling the MiNT 0.96 beta that Eric Smith released last Friday. When I type 'make', all C-files compile fine, and the 'asmtrans.ttp' and 'genmagic.ttp' programs get built, but the asmtrans program fails to translate the *.spp files to *.s files. The make fails after asmtrans reports `parse error'.
Anyone knows what's going wrong?
I'm running Howard Chu's recent versions of gcc and gas.

Thanks a lot, Hildo Biersma

In that case you will want your hard drive accesses as fast as possible,
and having 52000 sectors on a single partition will slow things down
considerably. I suggest you split your drive in partitions, perhaps
two: one for source files (sector size 1K) and one for your applications
programs, compiler, assembler etc. with 2K or more sectors.

Try reversing your Setscreen and Vsync calls. The Vsync will return at the START of a vertical retrace, if you then call Setscreen there should be no problem. This method has worked for me.

>> its consistant, unlike when i leave it out (then the flicker is really bad)

>> whats the solution?

You are drawing on the wrong screen. You are doing this:

```
Draw on A
Show screen B at next vblank
Vsync
Draw on B
Show screen A at next vblank
Vsync

Draw on A
Show screen B at next vblank
Vsync
Draw on B
Show screen A at next vblank
Vsync

etc.
```

>Try reversing your Setscreen and Vsync calls. The Vsync will return at the
>START of a vertical retrace, if you then call Setscreen there should be no
>problem. This method has worked for me.

This might work, but it it WRONG. The Setscreen call loads the screen pointer into a temporary location and sets the hardware at the next vertical blank (the one the Vsync() waits for).

This is also why "Vsync(); Setscreen(...)" might work - you are effectively saying "sync, then at the next vblank, update the screen to ...". ie:

```
Vsync
Show screen B at next vblank
Draw on screen B
Vsync
Show screen A at next vblank
Draw on screen A
```

This is fine.... until your update frequency drops below 1 frame per vbl... then you get a vblank occuring in the middle of "Draw on screen"!!!

Easiest solution is to switch to C++ and use AMS, which has encapsulated
Double Buffering... :-) :-) :-)

This is an easy one... some of the *.spp files have lines with just tabs in them.. remove the tab character and they will be processed with no problems!

I found this out last night when I did the same as you.

Er. Yes. You're right, and I should read my new AES documentation more
closely and more often. Sorry.

>I think we're also interested in WHEN this message will be sent. (I.e. not
>just when it CAN be sent but are we guaranteed we WILL get a message in a
>certain kind of situation?)

The docs say (I read them again) that the AES issues the message when the
new window is brought to the top. However, because we're talking about a
multi-tasking pseudo real-time system, there is no guarantee that the window
is still on top when your application receives the message.

Is this what you meant?

I use the ICD ADSCSI+, host adapter with clock, and versrion 5.6 of
the ICD software. My HD is in a WYSE PC-XT case and everything works
fine, on both my ST and my TT.

I have not followed all of your questions bu here is a summary of
things you may want to consider.

1) If your SCSI drive already has a case/PS adding any host
adapter except for the ICD LINK will require case modification
and a 50 pin ribbon cable.

2) If what you have is a SCSI HD sans case you will some kind of
case and PS. Used XT's make excellent cases and can be picked up
for about $50 with power supply. Then get the ICD ADSCSI, or ADSCSI+,
you will have to figure out how to mount it but that is reasonably
simple.

3) If what you have is a SCSI HD sans case you will some kind of
case and PS. Used XT's make excellent cases and can be picked up
for about $50 with power supply. Then get the ICD LINK, and a cable
to connect the LINK to your HD.

If your system is a regular ST, non MEGA, then you most likely do
not have a real-time clock. If this is the case I would recommend
option 2 with the ADSCSI+.

Price (as much as I can remember)
ADSCSI $90.00 (comes with ASCI, 50 pin ribbon cable, and power
adapter)

ADSCSI+ $120.00 (comes with ASCI, 50 pin ribbon cable, and power
adapter)

LINK $110.00 ($90 + required ASCI cable $20.00 additional)

All these host adapters come with ICD's driver and support software.
These are the best I've come across, I have to tried SUPRA HD software.

One word of warning, An ST will boot with the Drive as SCSI ID=0 the
TT seems to balk at it. If you leave the drive with ID=0 and then move
it to a TT the system does will not see the drive on a cold boot, but
does see it after a subsequent warm-boot.

>In that case you will want your hard drive accesses as fast as possible,
>and having 52000 sectors on a single partition will slow things down
>considerably. I suggest you split your drive in partitions, perhaps

What you say may bee a bit missleading! One can get the impression what you say
is that the accesstime increases with more and smaller sectors on a partition!

This is realy not so! I've been experementing a lot lately with partitionsizes
and sectorsizes. The fact is that the accesstime decreases when reducing
sectorsize without changing partitionsize (increasing number of sectors).
It also have a positive influence on transferrate of 'small' blocks, but
negative influence on transferrate of 'large' blocks! 2k sectors seems to give
the best overall performance out of my drive (connected to a TT)!
But you are right when you say that smaller partitions have better accesstime
than larger partitions, given that the sectorsize is the same!

4081. Writing an ACC with Sozobon 2.0

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-27 20:56:57 UTC
From: snoret@egon.unx.sas.com
Message-ID: <Bwssux.4rn@unx.sas.com>
Source record: 42230

I have finally gotten the time to begin learning how to program on
my ST. What I mean is learning the ST,GEM,etc. specifics. I've
programmed in C for a couple of years now, but always on UNIX boxes,
where all the linking, etc. was done automagically.

Anyway, here's my problem... I picked up a copy of the VDI and AES programming
guides at the WAACE swap room this year, hoping to finally write some GEM
stuff for my ST. I tried compiling the example desk accessory (somewhere
around page 200 of the AES guide). But no luck. The errors I got were what
I would normally consider a bit strange. It seems that the Sozobon 2.0
compiler didn't like some of the preprocessor macros. For example, the
error messages kept saying I was trying to redefine NONE, where none is

```
#define NONE -1
```

and it really barfed on the macros:

```
#define MAX(X,Y) ( X > Y ? X : Y )
#define MIN(X,Y) ( X < Y ? X : Y )
```

saying something like 'undefined value X' whenever the macro was used.

Am I missing something simple? (likely :) Is there some special preprocessing
I need to do? Do I need some special libraries linked in? Has anyone else
tried the example programs in the VDI or AES guides?

Any help would be greatly appreciated. (and maybe rewarded if I ever learn how
to program the DA I've thought of ;)

Thanks in advance,

Rick

4082. Need docs on installing TOS 1.4

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-27 21:01:10 UTC
From: gbernath@oucsace.cs.ohiou.edu
Message-ID: <1992Oct27.210110.11648@oucsace.cs.ohiou.edu>
Source record: 42240

I managed to get hold of a 6-chip set of TOS 1.4, but docs are missing and I need help. The 6 chips have different types of paper labels pasted on top, with the following printed on them:

Lo-0
L1-U6
Lo-2
H0/U4
H1/U3 (on top of another label saying L4-H1)
H2/U2

The question is, which chip in which socket? It's a 1040STf (if that matters). Please help!

Source record: 42239

Is anyone running PCDITTO 3.01 with a MONO monitor?

I get the copyright screen coming up on my mono, monitor, it asks for the dos disk, and then dies.

If I run it on a colour monitor (a t.v. actually) it does work.

Seems strange to me that the main screen will come up on a mono monitor but then not run.

How about 720k disks with PCDITTO 3.01?

Does it not support them?

I use the proper dos syntax and it gives me 'parameter not supported'.

Is this a dos message or coming from PCDitto (I'd vote for PCDitto).

>Bell Northern Research
>Research Triangle Park, NC

I think the original approach is the correct one, although I could be mistaken... Setscreen doesn't take effect until the next vblank hits & the screen is redrawn. By doing the Vsync *after* the Setscreen, you're effectively making sure that your code waits for the screen to be updated before it continues.

It could be that you're getting flicker because your screen memory isn't on a 256 byte boundary. I wrote the "shell" (for lack of a better word) of a game about a month ago, and ran into a flicker-like problem... My sprites/icons (whatever you want to call them) were showing up in two different places, depending on whether screen 0 or screen 1 was being displayed (for reasons I'll explain in a moment). Since I was using double-buffering for animation (i.e. I was flipping screens just about every vblank), the result was that each icon showed up half the time in one spot and half the time in the other, and would alternate rapidly between the two, causing a rather nasty flicker.

The solution was to insist that my extra page of screen memory was on a 256 byte boundary... When your pointer gets passed into the guts of your ST, via the Setscreen call, its 8 least-significant bits are cleared (for all intensive purposes, anyway -- no flames, please). Since my page buffer was not aligned on a 256 byte boundary, originally, the effect of this "lopping-off" was to shift my screen data quite dramatically, causing it to show up in a different position than it was supposed to. Hence, flicker.

If this isn't it, then I'm not sure what the problem is... If I got the Vsync/Setscreen info backwards, I apologize to Brian (the poster

of the first follow up) -- I think, though, that I got the order
correct.

Good luck...

John

It's been a while since I last asked these questions and things might have changed sufficiently to warrent asking them again. Please bear with me.

1. Is there an Ethernet board for ST/TT under TOS runing TCP/IP protocol that is available in the US? Are the SCSI Ethernet boards for the Macs workable on the ST/TT units? The service can be on demand only.

2. What tape backups are available for TT units? SCSI driver software? PD? Shareware? What kind (Brand, model, and capacity) of mechanism?

3. What needs to be done in order to execute a program in TT fast RAM? What tools are available?

4. Is there a version of GFA BASIC that supports the math coprocessor on an ST (as a peripheral device)? Is there one that supports the math coprocessor on the TT? Will this run under the TT RAM?

Thanks.

> connected, is bogus.

This may seem stupid but, have you disabled the other banks ?
Did you put the 33ohms resistor on the A9 line ?
Are you sure you took the right pin (A9) ?

If all this is all right, then I can't see any reason why it doesn't work !
Anybody else has another idea ?

> I know that some early MMU's could not address more than 1MB, but according to
> ST Format, where I got the information, my MMU has got the good serial number.

The MMU shouldn't be the problem (considering your ST is 87)

Oops, I answered to quickly !
There should be a 33ohm resistor between MMU and RAM.
I don't know the effect if there is no resistor, but this may be the error.

4090. PatchLevel 83 blues...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-28 05:16:29 UTC
From: anneklin@acs.bu.edu
Message-ID: <99745@bu.edu>
Source record: 42241

I've spent several hours today, trying to get my libraries for GCC up to speed (read: latest and greatest). I finally got through patching the sources from Update 24, and archived the whole lot, just to be safe.

I then started compiling (this is using GCC 2.2.2 pl 3 as compiled by Bjarne Pohlers). The first couple of dozen files just fly through, and then it gets to the first of the modules imbedded in the source file gnulib2.c. And it starts griping about a null character in the file string.h as included by gnulib2.c. And then it complains about a null character in the file string.h as included by the file string.h as included by the file gnulib2.c (this, of course, being an English translation)

Does anyone have any ideas? I ran across a problem with include extensions interfering with the pre-compiled headers capability once, but that's not what this is.

Suggestions?

Mike.

Huh? I've tried both my Q105lps and Q80s as ID=0 on both my SCSI
(internal) bus and on my ACSI bus - I have had no problems booting from
either one on cold bootup. Perhaps you were experiencing some sort of SCSI
conflict of IDs (two drives on the same ID)? Same with the original Seagate
157N.

>
>Does anyone have any ideas?

just one: whenever i start getting messages about errors that don't exist
(with gcc 1.40) i always assume i am running out of memory for the compile.
i have never been wrong (so far). one wonders what gcc does to my disk
cache during these occasional hiccups :-).

suggestions: 1) if compiling with -O, compile without optimization (which
uses less memory, 2) if not compiling on a 4 MB system, u might have run
to the limit, 3) fixstk on the cc1.ttp executable (i assume 2.2.2 still has
one of these), 4) split the file, 5) cross compile on a unix host, 6) compile
from the desktop (yuck) sans DAs and TSRs (and ramdisks). as a very crude
rule of thumb, i have found that on a 4 MB mega with ~256KB of various
caches, MiNT, and tcsh that i run into problems with src code larger than
about 100KB (itself a rather large file as things go). examples are GNU
regex.c and large grammars (output of bison). it also might not hurt to
attempt the compile immediately after a reboot (when there is the least
memory fragmentation on the system and hence the largest Malloc'able chunk).
i have also solved similar problems by invoking gcc directly rather than
thru GNU make (hence adding the memory make would take).

note that generally, bammi and others do not compile gcc code on the st.
they cross compile on "real" workstations. i ran into a problem like this
when attempting to compile gawk or bison (forget which had the large file).

of course there could always be a bug in gcc, tho i have found 1.40 to be
extremely stable and reliable...

Don't use TOSWIN initially. It messes up the GEM system: it confuses fonts of other applications and it pops up its menus when it's not allowed to. I found out that running Gemini, Gemterm, Turbo ST and MiNT together is all right, as long as you leave TOSWIN out. (Sometimes you'll have to disable Turbo ST for otherwise programs will still write directly on the screen.) Just use Gemterm until yours truly finishes his xterm-clone (plan to call it `ST Lauder') for MultiTOS somewhere this or next week. It will be a lot more compatible and GEM-neat than the other two but has a different approach (it actually IS an xterm as on your UNIX machine.)

> I'm running Howard Chu's recent versions of gcc and gas.

I had exactly the same problem. I found out that the .spp files that
caused the parse error had one difference to those who did not: the
inclusion of the file magic.i. So I looked at the magic.i written out by
genmagic.ttp, and it looked a bit strange, in comparison to the magic.i
originally included in the archive.
Then I cancelled the genmagic procedure from the makefile and took Eric's
original magic.i, then everything went fine. But I'd like to know why
the generated magic.i is broken and what consequences this might have!

Regards, Markus.

>P.S I read this in a Amiga(Games Machine) newsgroup, looking for
> information about new computers from CBM.
> Their newest computer is the A1200 - 680ec20
> - no DSP
> - no SCSI
> And they say its a Falcon killer !!! (HaHa)

Well.. Here are some clues for you:

1) The 14MHz 68EC020 in the A1200 performs better than the Falcon 16MHz 68030 because of the dual-bus design. The A1200 is around 4 times as fast as the A600. The Falcon is only about 2 times as fast as the ST. The ST is about as fast as the A600. Go figure...

2) In a low-end system (like the A1200) a SCSI interface is a waste of money. Most people buying an A1200 will make do with an IDE HD or none at all. If an A1200 owner wants SCSI (s)he will buy an expansion card.

3) The AA Chipset beats the hell out of the Falcon Gfx chips, period.

4) A DSP and 16-bit sound is a total waste in a low-end system. Most users will use a TV set, and with the limited sound quality of most TV sets I don't think you ever will be able to hear any difference between 8-bit and 16-bit sound. Also, keep in mind that 16-bit sound takes TWICE as much memory as 8-bit sound does. With the Falcons 1MB of RAM I don't quite see how you're supposed to get any amount of CD-quality sound (which is what all Atarians are raving about) into games. I mean, with 1MB of memory you will only be able to store 23 seconds worth of *MONO* CD-Quality audio! But then you have no room for Gfx or code ...

5) It's *AVAILABLE NOW*! I've heard about the Falcon for months now, but I still haven't seen it sold anywhere ... What good is a computer that you cannot buy? The A1200 is being introduced in England and Germany next week! Price in England: 399 pounds.

6) Since the A1200 runs every available piece of software as well as the new AA-specific software it's got a significant advantage over the Falcon as far as software support is concerned. [Atari is a dead duck over here]

7) Major entertainment software producers have pledged support for the
new graphics capabilities of the A1200 (We in Team17 included). That's
more than you can say about the Falcon ...

The new version of TOSWIN (v1.4) fixes this problem. It's available
as toswin14.zoo on atari.archive (it's in the New/ directory now,
and will be moved over to Mint/ soon I'm sure).

I've also uploaded the source code for TOSWIN; it's in toswinsc.zoo.

> workable on the ST/TT units? The service can be on demand only.

There's PamsNet, an Atari ST ethernet network that uses its own protocol. However, PAM software, who develop and market this network, also offer TCP/IP for PamsNet. However, we don't use this here, so I can't tell how well it works.

>2. What tape backups are available for TT units? SCSI driver software? PD?
> Shareware? What kind (Brand, model, and capacity) of mechanism?

I have no idea, and am interested in this myself.

>3. What needs to be done in order to execute a program in TT fast RAM? What
> tools are available?

To my knowledge, in byte #25 (byte counting starts with 0) of a program file, the least three bits are the following flags:
Bit #0: "fastload", the TPA will not be cleared before the program code is executed.
Bit #1: "TT-prg", the program will be loaded into TT ram, if available.
Bit #2: "TT-mem", memory allocated by the program will be in TT ram, if possible.
If this info is not in the FAQ, it should be considered to be included, IMHO.

There are various goodies (programs, accessories , CPXes) floating around that can set these flags, you normally should not have to mess around with file monitors to manipulate them. If you write the programs yourself, most linkers have options to set these flags these days.

>4. Is there a version of GFA BASIC that supports the math coprocessor on
> an ST (as a peripheral device)? Is there one that supports the math
> coprocessor on the TT? Will this run under the TT RAM?

About the math coprocessor in an ST I don't know, but I assume there is no GFA support of it. Regarding support of the TT's FPU, the answer is yes, GFA basic version 3.6 TT produces code that uses the FPU if it detects one, but you have to include the ~TT?

call in your program. However, GFA Basic 3.6 is kinda buggy, it seems that GFA Systemtechnik has ceased developing GFA Basic for the ST before version 3.6 was properly debugged. The good news about this is that another software house, Richter, will continue to support and develop GFA basic for the ST, and they're in the process of taking care of all the problems.
GFA 3.6 programs can run in TT ram, and the linker enables you to set the TT ram flags as mentioned above.

If you think it through, you'll realise you're wrong here. Setscreen
has to return from it's trap before vsync executes. so how's it
supposed to make Setscreen wait? By doing a Vsync after, you're just
wasting time waiting for a second screen refresh.

According to the German computer mag c't this is N O T true. In one of the
first detailed articles about the FALCON (some months ago) they state that
the FALCON has 32bit RAM Access... it seems they found out by taking a close
look at the timing (or something else; sorry, I not too much into technics
and it's been some time since I've read the article).

Greetings,

Yes, PC Ditto works fine with a mono monitor. It must be set up
correctly first in the PCDMenu program. (I think the name is right, it
has been a while.)

>How about 720k disks with PCDITTO 3.01?
>Does it not support them?
>
Yes, you have to load the right PCD disk device driver. This will add
a new drive letter to the end of your current drive chain. The drive
must be accessed by that letter if you want to format a 720k disk.

>I use the proper dos syntax and it gives me 'parameter not supported'.
>Is this a dos message or coming from PCDitto (I'd vote for PCDitto).
>
Don't know, what are you trying to do? What DOS are you running?

All of these questions (except the last one) are covered in the PCD 3.01
manual (which is rather thin and not a stretch to read). I am hoping
here that you don't have a manual (as opposed to just not reading it
and posting these basic questions to the news group instead).

4105. PDS slot in Falcon

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-28 14:54:16 UTC
From: d91-jsn@ludd.luth.se
Message-ID: <1992Oct28.145416.3630@ludd.luth.se>

Since I have red so many different specs on the PDS slot in the Falcon I would like to ask somebody with HANDS ON experience to write down the specs.

I have heared everything from that it's a very stripped bus merely able to connect a slo-nothing-to-car-about- processor to a full blown 32 bit ninja everything bus...

I would also know that the 65K color mode really isn't avaliable in higher res than 320x200 (I know this is lame, but I have three different copies of ATARI RELEASES and they all have different Resolution/color specs...)

Thanx dudes!

> fast as the A600. The Falcon is only about 2 times as fast as the ST.
> The ST is about as fast as the A600. Go figure...

First of all, have you ever performed benchmark tests on a Falcon? If not, how on earth can you comment on something you don't know anything about? You can not base any conclusion on the limited informations posted here on the net. Secondly, the A1200 comes (when you can bye one!) with only chip-ram, so the cpu and the chipset has to share the same bus just like on the Falcon (there goes that speedup factor). OK! you could spend your savings on a FAST RAM upgrade, but there goes the expansion slot! (and you can not be sure that the programs will make use of the extra memory). And finally the MC68030 IS faster than the MC68EC020 (that is at the same clock - but the A1200 goes at lower clock that the Falcon) and it's has a MMU so we can get useable multitasking on the Falcon (Not like on the Amiga - was it software failure you called it?)

> 2) In a low-end system (like the A1200) a SCSI interface is a waste of
> money. Most people buying an A1200 will make do with an IDE HD or
> none at all. If an A1200 owner wants SCSI (s)he will buy an expansion
> card.

SCSI is a very cost efficient way to expand you computer with a huge range of add-ons, so I see the SCSI interface as a very good move by Atari. But then the lack of expansion abilities (remember that we used the expansion port for extra memory so you could get your speedup from the dual bus!) on the A1200 goes very fine with the Commodore strategy (That is - Here you got a machine, and if you want to expand it, you have to buy another one from us!) just like the A600. OK it could be that Amiga owners don't need that much expansion abilities, after all most of them only us it to play games on.

> 3) The AA Chipset beats the hell out of the Falcon Gfx chips, period.

Pardon, in what way? Yes the AA has more colours, but to what use? you can only show 256 colours on the screen in any useable modes (you will not get my to call any HAM-modes useable!) so it's just like on the Falcon.

The resolutions is allmost the same on the two machines, and before you start screaming - no! the Falcon DO HAVE bigger resolutions than 640X480x256. And by the way, the AA blitter is not only the same as in the old Amigas, but it goes at the same clock (7. something Mhz). So you have

a blitter that as to move 2-4 times the amount of data at allmost the same transfer speed. The Falcon BLiTTER may not be as advanced as the Amiga one, but it does go at 16Mhz.

> 4) A DSP and 16-bit sound is a total waste in a low-end system. Most

> games. I mean, with 1MB of memory you will only be able to store
> 23 seconds worth of *MONO* CD-Quality audio! But then you have no
> room for Gfx or code ...

You are just far out on this one. If you don't want 16bit sound that's fine with me, but the most of us are looking forward the get CD-quality sound in our games. And when it comes to the sound output, I just plug it into my stereo set and then we go!

You say that 16bit sound will use all the memory in a 1MB Falcon, but then somethings don't add up. Amiga use 8bit for sound so acording to you, games uses 512Kb for sound (I can understand why you have all sound data in the memory, when I think about the speed of the Amiga's disk drives). But then most Amiga's only have 512Kb of RAM! Are you then saying that you can't play any games on these machines?

Maybe you don't have that much use for a DSP in a game computer (beside for greate sound), so I can understand why Commodore didn't included one o=in the A1200. But for the rest of us who uses our computer for a lot more than just playing games (not that I don't like a great game!), a DSP is very usefull for a lot of purposes.

> 5) It's *AVAILABLE NOW*! I've heard about the Falcon for months now, but
> I still haven't seen it sold anywhere ... What good is a computer that
> you cannot buy? The A1200 is being introduced in England and Germany
> next week! Price in England: 399 pounds.

Oh! you can get a A1200 now, but you have to wait until next week, or will it be week after that or .... The point is that I don't care if you can buy one machine a week or two before another. You know, I don't eat computers.

> 6) Since the A1200 runs every available piece of software as well as the
> new AA-specific software it's got a significant advantage over the

> over here]

What AA-specific software? I haven't seen or heard about anything yet. And you do know that Falconn runs ST software very well?

If you think Atari is dead in Sweden (I surpose that's what you mean with 'over here') or for that matter in Denmark or Norway, you simply don't know what's going on outside your own door.

> 7) Major entertainment software producers have pledged support for the
> new graphics capabilities of the A1200 (We in Team17 included). That's
> more than you can say about the Falcon ...

Oh silly me! I did not realise that you were spokesman for all the software
producers. I don't care if Team17 don't support The Falcon, cause a many
others do, and I am confident that I will be able to get all the software
for the Falcon that I want.

According to some docs about the F030 I read, the PDS slot has all important bus-signals from the 68030, 16 bits wide databus and 24 bits addressbus.
(If I remember correctly)

sigh ... I don't usually answer mindless flames, but I've had a
hard day, so here I go... :)

boberg@lysator.liu.se (Stefan Boberg) writes:
: anderss@colargol (Anders Skar) writes:
:
: > Is it true that the Falcon030 only has 16 bit RAM Access ?
:
: I don't think so.
Definetely not!!!

: >P.S I read this in a Amiga(Games Machine) newsgroup, looking for
: > information about new computers from CBM.
: > Their newest computer is the A1200 - 680ec20
: > - no DSP
: > - no SCSI
: > And they say its a Falcon killer !!! (HaHa)
:
: Well.. Here are some clues for you:
:
: 1) The 14MHz 68EC020 in the A1200 performs better than the Falcon 16MHz
: 68030 because of the dual-bus design. The A1200 is around 4 times as
: fast as the A600. The Falcon is only about 2 times as fast as the ST.
: The ST is about as fast as the A600. Go figure...
:
The Falcon 030 is 3-5 times as fast as the 8MHz Atari ST, depending on the
graphics mode, and of course on what you do - it can be 100x faster if you
employ the DSP...

: 2) In a low-end system (like the A1200) a SCSI interface is a waste of
: money. Most people buying an A1200 will make do with an IDE HD or
: none at all. If an A1200 owner wants SCSI (s)he will buy an expansion
: card.

Why? The price difference between SCSI and IDE drives is so small these
days, that I can't imaine anyone preferring the obsolete IDE interface
over the STANDARD SCSI! Except perhaps if they want 2,5" drives, where
at this time, IDE is most commonly used.
BTW, how much will that SCSI extension card cost for the A1200? :)
$50? 100? :)

: 3) The AA Chipset beats the hell out of the Falcon Gfx chips, period.

Yeah sure! That's the kind of arguments I like (with no facts, only stupid
announcements!). How about comparing screen modes?

: 4) A DSP and 16-bit sound is a total waste in a low-end system. Most
: users will use a TV set, and with the limited sound quality of most
: TV sets I don't think you ever will be able to hear any difference
: between 8-bit and 16-bit sound. Also, keep in mind that 16-bit sound

If you want to use a TV, that's fine. I'll connect my Falcon to my amplifier
(most people have one). And I also like the possibility to sample sounds
without any additional hardware in 16 bit stereo!

: takes TWICE as much memory as 8-bit sound does. With the Falcons
: 1MB of RAM I don't quite see how you're supposed to get any amount of
: CD-quality sound (which is what all Atarians are raving about) into
: games. I mean, with 1MB of memory you will only be able to store
: 23 seconds worth of *MONO* CD-Quality audio! But then you have no
: room for Gfx or code ...

Only that the DSP is able to (de-)compress sound with no obvious loss of
quality by 10:1 or more in REALTIME! And with no CPU time wasted!
And the standard Falcon will have 4Mb anyway!

: 5) It's *AVAILABLE NOW*! I've heard about the Falcon for months now, but
: I still haven't seen it sold anywhere ... What good is a computer that
: you cannot buy? The A1200 is being introduced in England and Germany
: next week! Price in England: 399 pounds.

Haha! :) Next week, eh? At least I've seen and tested a Falcon for hours,
and I could have ordered one already!

: 6) Since the A1200 runs every available piece of software as well as the
: new AA-specific software it's got a significant advantage over the
: Falcon as far as software support is concerned. [Atari is a dead duck
: over here]

Yeah, sure! I've heard that quite a few former A500 users complained that
half their software doesn't run on the A600 anymore! And now you'll get
more problems because of the different processor! The EC020 isn't even
capable of memory protection BTW, it doesn't even have a PMMU!

: 7) Major entertainment software producers have pledged support for the
: new graphics capabilities of the A1200 (We in Team17 included). That's
: more than you can say about the Falcon ...

You think so? Many Amiga and NeXT developers have announced that they'll
develop software for the Falcon, even Macintosh developers!

: I've got a 68040 in my A4000. Does a 68040 Atari even exist? Didn't think
: so.

Wait and see, that's all I can say! :)

-MY

Problem solved--just a farking trailing backslash in TEMP.

One thing, though--I had a few of the tests fail for me, though I didn't have any compilation errors. Is this the compiler, or have the test files not been reconciled with PatchLevel 83, or what. Right off the top of my head, trandm.ttp failed, as I think did strtl2.ttp and tstdio.ttp.

Mike.

4111. Re: 16-bit RAM Access on Falcon ?

And you to, Stefan, need to get som clues:

> 1) The 14MHz 68EC020 in the A1200 performs better than the Falcon 16MHz
> 68030 because of the dual-bus design. The A1200 is around 4 times as
> fast as the A600. The Falcon is only about 2 times as fast as the ST.
^^^^^^^^^^^^^^^^^^^^^^^^
Where did you get this totaly wrong figure from? The figure is 4-5 times
faster than a plain 8MHz STe, and probably some 5-7 times faster than a plain
8MHzST!

AND, the M68030 is at least 33% faster than the 68020 when using synchronous
memory access (020 dosn't hav this), and even faster when using burstmode to
fill caches.
And there are only Instruction Caches on the 020, but both Instruction and Data
caches on the 030! (I'm not shure though that the 68EC020 has cache at all)?
Then there is the advantage of the PMMU inside, allowing virtual memory,
memoryprotection between processes and other nice stuff...

I deleteded (and won't comment) the rest of your message, because what you
REALY say is that a low end machine like Falcon 030 is no good because it has
to much good stuff included to be a real **LOW** end machine like your Amigas!!!

Well, I like to think of the falcon 030 as a **HIGH** end machine for
a **LOW** end price!

4114. HELP! MiNT novice and tcsh/mintsh

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-29 00:18:32 UTC
From: jmillar@rodin.helios.nd.edu
Message-ID: <1992Oct29.001832.16521@news.nd.edu>
Source record: 42267

Hello! I am a complete novice with MiNT. I _do_, however, use UNIX quite a bit, so I am familiar with the use of cli's, csh specifically. Repeat, the USE of csh, not the inner workings of it.

I recently D/L'ed MiNT v0.95, some of the utilities, and tcsh from a.a. I installed MiNT on my brother's MEGA/STe using TOSWIN and the supplied mintshell. I then placed the utility programs in the /mint/bin/ directory on the root partition of his hard drive.

Under TOSWIN, mintshell worked perfectly in executing the programs in the /mint/bin/ directory I had installed. However, whenever I attempted to invoke tcsh as a cli, it would load up, a window would open, but the program would immediately be exited.

What do I have to do to run tcsh as a cli under TOSWIN? Is there a TTP parameter that I must specify on the command line when tcsh is opened in order to get it to work? Must I have specific files in specific directories , or what? What do the logon and logoff files that came with the shell do exactly? Are there specific environment variables that I must set? Do I have to change a parameter specified in the MiNT configuration file?

Also, what are the benefits of using tcsh as opposed to mintshell? I'm guessing that since it is a much larger file that it is a much more complete shell (pipes, etc. automatically supported instead of using an external program.)

Well, those are the questions I have, and I would greatly appreciate any advice that any MiNT gurus could give me. I hope I didn't insult anyone with my ignorance of the inner workings of UNIX-type OS's or the like. I use UNIX simply because I HAVE to....not because I like it that much. :)

Thanks.

Uhhh,what a horrible idea...
Yesterday,my friends said to me that our programming-project is to
develop a
grafix-converter for ST/TT/FALCON with C.But none of us has a Source for
any
grafix-format (...and any idea how to programm in C,of course).So,is
here
(or there,dunno) somebody how have some info about 1 or more
grafix-format
or access to this or know there i can get such information?
Any help will highly appreciated.
Please send me some docs fast,cause i have to programm it fast,too.

Thanx in advance...

...and CU on IRC!

4116. mono vs r/f modulator

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-29 01:26:57 UTC
From: Mike Stramba <stramba@zooid.guild.org>
Message-ID: <1992Oct29.012657.1037@zooid.guild.org>
Source record: 42280

What is the difference, if any as far as Tos or Gem are concerned when running either a colour or mono monitor from the standard video jack OR using the r/f modulator jack?

Is there built in screen memory or other hardware for the r/f modulator?

> 68030 because of the dual-bus design. The A1200 is around 4 times as
> fast as the A600. The Falcon is only about 2 times as fast as the ST.
> The ST is about as fast as the A600. Go figure...

The Falcon is 3 to 5 times as fast as an ST, depending on applications.

> 4) A DSP and 16-bit sound is a total waste in a low-end system. Most
> users will use a TV set, and with the limited sound quality of most
> TV sets I don't think you ever will be able to hear any difference
> between 8-bit and 16-bit sound.

Typical Ameagre owner logic! Gee I wish the Falcon only had PC 2-bit sound,
that way I wouldn't waste it! *-)

> Also, keep in mind that 16-bit sound
> takes TWICE as much memory as 8-bit sound does.

If you use it, dweeb. Falcon supports right down to 8-bit mono, but apart
from that, the DSP can do real-time decompression of sound, so THERE!

> With the Falcons
> 1MB of RAM I don't quite see how you're supposed to get any amount of
> CD-quality sound (which is what all Atarians are raving about)

Direct-to-disk and direct-from-disk is possible on the Falcon030., and anyone
wanting more RAM can simply buy it.

> 5) It's *AVAILABLE NOW*! I've heard about the Falcon for months now, but
> I still haven't seen it sold anywhere ... What good is a computer that

NOW != next week, Bucko.

> 6) Since the A1200 runs every available piece of software as well as the
> new AA-specific software.

B\/LL$HIT! Not even the A3000 is capable of running a lot of A500 s/w.
Incompatibility is inevitable... unless you go into the (8088-2)*9+7512+100
market!

> 7) Major entertainment software producers have pledged support for the
> new graphics capabilities of the A1200 (We in Team17 included). That's
> more than you can say about the Falcon ...

No it isn't. Many developers have also "pledged support". And those are
not all "entertainment software" developers either.

Since the 68020 doesn't have an MMU in it, the A1200 will probably have
the typical unprotected multitasking of the old amigas, and no vram option.

4119. Very General uucp question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-29 03:00:32 UTC
From: bq035@cleveland.Freenet.Edu
Message-ID: <1cnk4gINNnmn@usenet.INS.CWRU.Edu>
Source record: 42268

I think the subject says it all. Can someone provide or direct to answers to
these questions:

* what reasonable machine requirements are
* what you need to have access to (modem types, host machines, etc.)
* basic outline of what is involved with uucp (the actual process)
* finally, what does one need to know to be able to set one up.
* is there a good uucp program with English docs?

Ich glaube, daB es gluecklich ist, daB ich ein bischen Deutsch lesen kann!

I imagine that I'm not speaking for myself when I say that, due to the questions
I've been seeing lately, that the process seems very intimidating.

All I've been able to suss out is that I will need to read German, understand a
little about the Internet infrastructure, and have access to a machine which I
can send my data through. Otherwise, it seems about as clear as mud.

If I *ever* figure this out, I'll post a lucid summary (auf Deutsch :)

4120. More on the GCC libraries...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-29 06:03:48 UTC
From: anneklin@acs.bu.edu
Message-ID: <99935@bu.edu>
Source record: 42269

Ah, the thrills and chills of doing it yourself...

I've gotten the PatchLevel 83 GCC libs compiled. They even pass all but three of the tests. Find and dandy.

Now I want to compile the PatchLevel 14 C++ libs (BTW, Warwick, you should hold yourself completely responsible for my trials, 'cause it's your AMS library that I want to play with--all this other stuff is just in the way).

Unfortunately, whatever auto-dependency generator is run to produce the file mincl, well, it seems that it screwed up. On the first line of the dependencies (just below the "Do not put anything below this line" line), Make tells me that there are multiple targets (or was it multiple dependencies) and croaks. Has anyone gotten any of these makefiles to work?

While I'm at it, I've got a suggestion--most of the stuff that's common to the makefiles has been moved into the various mincl files in the various source modules. Wouldn't it be simpler, though, to move all the environment specific stuff out of the makefile. Say, arbitrarily take over an environment variable MAKEDEFS. This variable should point to a make include file that defines certain standard variables (CC, AS, MAKE, GNULIB, whatever) for the particular environment (thereby removing so many of the references to subdirectories on ++jrb's Unix box). Then, at the beginnning of every makefile, do an "include $(MAKEDEFS)". Suddenly, with a little planning, you can have all the necessary stuff in one file, and all the makefiles for all the GNU stuff would automagically configure themselves to your environment.

Or maybe I'm just blowing sunshine.

Mike.

>(If I remember correctly)

The PDS is a 68000 bus slot. There are no 68030-specific signals there, it is all 68000-oriented. 16 data bits and 24 address bits.

The true color modes are available in all the resolutions if you're using a TV or SC1224. If you're running in VGA mode then you can only use the 320/384 pixel wide modes.

2 times th espeed of the ST????? get a life!!! where do you have that
from???? Rating of falcon is about 470% speed increase. I am pretty sure
that you have your info from advocacy, which is domonated by dorks.

AND as I have heard, the A1200 will come with 2meg chip-mem so you can not
make use of the extra bus if you do not buy fast-mem, which most amiga
players won't. Because they don't need that and they don't need that. Why
should companies produce machines and software, people can build whatever
they need, and make the software they need..... like boberg says........

This is always a problem but the ``slap them a charge 'cos then they must
really need it'' band always get -10 from me for customer relations.

> As it turned out, the problem wasn't with the DMA chip after all, but
>was an over-heating PSU. i only realise this when i got a new Quantum and
>put it in with the other drive. Installing a fan cured it (fingers X'ed)

On to more serious stuff... I had a problem with an ICD SCSI adapter and a
quantum(? memory's failing) drive. It would fail after being switched on
for a time both on rd & wt. I eventually put it down to the drive as it
would fail on other ST's and ICD adapters but I have this niggling doubt
as it finally found a home on a non ST system & is alive and well. I concluded
my system had a clean bill of health as I have other drives which perform
faultlessly.

Anyone any ideas or similar experiences?

John

Actually, I'm right... Of course Setscreen returns before Vsync is
even called. My point is that the changes that Setscreen *causes*
don't take effect until the next vblank...

Setscreen (in this context) causes the system's pointers to screen (&
buffer) memory to be changed. If Setscreen took effect
"instantaneously" (in some sense) you might run into a situation where
your screen gets garbled because the system's notion of screen memory
has changed halfway through the redraw (I'm not entirely sure of the
ramifications, but I think the idea is valid). What happens, instead,
is that the new pointers are used on the *next* vblank, so that the
whole screen is redrawn based on the new pointers.

By doing the Vsync after the Setscreen, you're forcing your code to
wait until after the new pointers have been used... i.e. you've

waited until it's safe to start drawing on the non-displayed page of screen memory.

In case you're wondering, I've actually tried both schemes & believe me -- Setscreen ... Vsync (in that order) it works. Vsync ... Setscreen (in that order) doesn't.

Date: 1992-10-29 20:05:55 UTC
From: grier@bnr.ca
Message-ID: <1992Oct29.200555.666@bnr.ca>
Source record: 42282

The RF modulator jack only puts out a useable signal in color modes. It puts out a signal when a monochrome monitor is used, but the information is garbage.

Basically the RF modulator allows you to use your TV as an alternate monitor.

With regards to the "Setscreen and Vsync" message I posted.
I went back to my code just knowing I had posted the way my code was written...

Alas I screwed up!! Please ignore my post.

Hello everybody,
As I intend to do a lot of programming in the near future on my atari
I'm looking for some libraries that support gem programming.
I would say like to have a function that dispatches my events and one
that installsredrawfunctions on windows etc.
You get the drift?
Such a lib could save me a lot of time (otherwise I would have to write it
myself...).
I've heard of one such lib called MAGIC or such for modula-2.
Does anybody have anymore info on this one. Is it PD /ShareWare/Commercial
and how can I get it?
Are there equivalent libs?
I prefer PD or Shareware.
The language should be either modula-2 (I really like it) or c.

Can anybody help me with my search?
I will summarize any answers I get...

Thnx

From: baffoni@phakt.usc.edu
Message-ID: <1crvi6INN761@phakt.usc.edu>
Source record: 42096

Hi all,

Like many others seem to have done recently, I decided it was time to have a multi-tasking Atari, with available CLIs too.

So I downloaded MiNT .95, various and sundry utility archives, Eric's (I believe) TCSH, and the new TOSwin1.1.

Reading through the docs (I realize I shouldn't do that until all else fails, but I thought I'd get a jump-start on my problems. :), I got the mint.cnf happy, and tcsh happy with mint.cnf - tcsh has a path to /bin where all the necessities are kept (ls, cat, less, etc.). However, I have noticed a couple of problems that must be too simple for me to figure out.

If I try to run any .prg from the desktop as per normal operation (I do not boot up any other programs, so it goes to GEM by default) it will "lock up" - nothing is happening, but I still have mouse control - it just doesn't do anything. I can run tcsh.ttp ala toswin, and can use it to launch programs, but gem programs behave oddly. For example, when I launch connect.prg, and I try to select a menu using the mouse, the drop-down menus work fine, and highlights my selection just fine, but nothing happens. I can get everything to work normally when I use keyboard equivelents however.

My system is a TT with TOS 3.06, and all I run in the /auto are the boot software and MiNT, the only .acc are TOSwin1.1 and xcontrol.

So am I forgetting something obvious here?

-Mike

>has to return from it's trap before vsync executes. so how's it
>supposed to make Setscreen wait? By doing a Vsync after, you're just
>wasting time waiting for a second screen refresh.

NO NO NO NO NO!!!!!

The Setscreen call puts values in a temporary location, then returns
immediately. At the next vblank, DURING THE OS VBLANK ROUTINE, the
values are copied from the temporaries into hardware registers. The
Vsync() is needed to wait for this OS vblank routine to occur. It might
seem like wasting time, but if the frame has been drawn and can now be
displayed, what else is left to do? Of course, you could use triple
or quadruple buffering, but those techniques only give gains in a few
circumstances.

Don't you remember all that stuff from the 8-bit machines? They were
called "Shadow registers".

One more time:

```
Setscreen(...)
THEN
Vsync()
```

4141. Cross compiling sozobon C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-30 13:09:30 UTC
From: richard@op.ph.ic.ac.uk
Message-ID: <1992Oct30.130930.27021@sol.ctr.columbia.edu>
Source record: 42091

Has anyone successfully cross-compiled sozobon 2.0 on a sun?

I thought I had it all working using old libraries, but now I've
compiled the mint library, I've noticed a problem... and it's not
with the library.

The symptoms:

If I nm the old dlibs.a I get:
```
**********************************
(abort.o):
0 glb text _abort
0 ext abs _raise
0 ext abs _exit

(abs.o):
0 glb text _abs
1a glb text _labs

(access.o):
0 glb text _access
0 ext abs _stat
0 ext abs ___mint
.
.
.
**********************************
```

but if I nm the new dlibs.a I get this:
```
**********************************
(abort.o):
0 glb text _abort
0 ext abs _raise
0 ext abs _exit

(abs.o):
50014 ?0? > notice this
87654321 text SozobonX > garbage
0 glb text _abs

(access.o):
0 glb text _access
0 ext abs _stat
0 ext abs ___mint
.
.
.
```

```
**********************************

The garbage in the file occurs for every other .o file in the
library.

But that's not all... If I create a small file test.c and cc -c it
and nm the test.o file with another file (say the old dstart.o which
shouldn't be corrupt) then

nm lib/dstart.o test/test.o gives
**********************************
lib/dstart.o:
0 glb text __start
40 glb text __setsta
48 glb text __monsta
48 glb text __moncon
48 glb text ___mclea
0 glb ext abs __app
0 glb ext abs __base
0 glb ext abs __heapba
0 glb ext abs __stksiz
0 ext abs __acc_ma
0 ext abs __crtini

test/test.o:
0 glb text _main
0 ext abs _printf
**********************************

which seems fine, but

nm test/test.o lib/dstart.o
**********************************

test/test.o:
0 glb text _main
0 ext abs _printf

lib/dstart.o:
50014 ?0? < more garbage
0 glb text __start
40 glb text __setsta
48 glb text __monsta
48 glb text __moncon
48 glb text ___mclea
0 glb ext abs __app
0 glb ext abs __base
0 glb ext abs __heapba
0 glb ext abs __stksiz
0 ext abs __acc_ma < last entry missing
**********************************

(nm on two good .0 files works fine).
```

Now this isn't the fault of nm, or ar, but most likely jas,
does anyone no what I have to do to correct it?

Thanks
Richard

4142. Re: Cross Compiling Sozobon 2.0

Source record: 42093

Please ignore that load of stuff I posted a short while ago - I've sussed
the problem (thanks Mike...)

nm IS having problems, the readon I didn't think it was, was becuase I also
couldn't compile anything using the new library... but I hadn't looked
very carefully at the error message - it was actually a minor incompatability
between sozobon and the mint lib source...

OK people so why does sozobon ignore the 'long _initial_stack'
declaration in mntlib's inistack.c. (It doesn't make it through to
the lib) And also, is it OK if I just change
the 'extern long _initial_stack' in crtinit.c to 'long _initial_stack'.

Apparently this was changed for patch level 22, will my st have problems
if I change this?

(Mr E.Smith?? I've heard you're not quite a Dr yet ;-)

This refers to some phone contacts with PARAGON Computer's
in Perth Western Australia...

This is the bigest distributer of Atari Computers in OZZ..

I contacted them back in May/June about getting TOS 2.06,
they informed me that they were getting some from Atari OZZ soon.

I contacted them again on Monday the 26th Oct 92...

A friend would like his Mega STE upgraded to TOS 2.06 and a 1.4 meg drive..

I have heared that there are kits for this in the USA...

Well Paragon stated that there was a 2 year waiting list for 1.4 meg drives,
or some thing to that effect, I then asked about TOS 2.06, he stated that
Atari OZZ had let them down and they were hoping to get some from Compo U.K.

I also asked about the replacment GAL chip, and the chap stated what GAL chip
! never heared any thing about a new GAL..??

I also aked if it was true that we were getting a Demo Falcon here in NZ. in
November, he stated that this was very unlikely and it would be
about February 93, before we saw Falcons out here, OZZ/NZ...

NOTE: Bob Brodie the Communication Director for Atari USA, stated to me

that If I needed Atari support here in New Zealand that I should go
to Atari OZZ or PARAGON Computer's...

I have allready delt with Atari OZZ and it took 12 Toll calls to get
replacment DMA chips, also there Service manager did not know what TOS 2.06
Roms were...???

Tell me is this Support..???

So tell me chaps do you think that people should stick to Atari, if you do you
must nead your head seeing to...

Roger.............. sheppard_r@kosmos.wcc.govt.nz

Subj: ATARI's future

Dear ATARI users,

I am sure you are aware that I am no longer working at ATARI Corp.
Different personal and inner company reasons made me do this, not so easy
a step.

I understand the current German ATARI market is categorized as one of
the strongest markets anywhere, and I am sure that makes it hard to
understand why I left. I appreciate your feelings deeply. My decision to
leave ATARI was strengthened as a result of it being decided to stop
FALCON production because people noticed that the planned customers
weren't ready to invest between 2300 and 3500 German Marks ($1300 and
$2000). These persons would most likely buy a MS DOS compatible computer
or even a Macintosh instead of putting a low end machine with very limited
uses in their house. At this time however, a few FALCONS are being
delivered to a few select, handpicked German dealers, these belong to the
first production run and are without, as announced, MultiTOS. Instead,
they are being delivered with the single tasking TOS 4.0x. The number of
machines are limited and will be the only ones available for the time
being. You most likely will not understand this unusual strategy, but why
should we produce thousands upon thousands of FALCONS that can't be sold?

The FSM-GDOS and MultiTOS production had to be stopped in the last
minute because 1) a renegotiation with Mr. Eric Smith (copywrite) and 2)
differences between ATARI and Bitstream. Naturally ATARI knows that
MultiTOS, for the entire semiprofessional area, shouldn't be
underestimated and that the MT project will be taken up again.

The SUTRA project is still under high pressure development and should come out around the first of April 1993.

The entire ATARI product line is still going to be 'fully supported' as much as possible, although the 68030 class of computers will have to be held back until it is believed they have a fairly good chance in the market. At this time, the need for powerful machines seems to be satisfied by the TT and ATARI is having it hard enough as it is. I hope I was able to give you a small picture into ATARI's future and I beg of you not to doubt in ATARI's credibility. Think positive!

I wish you all much luck

a friend of mine needs to sell his ST to get some money towards a falcon
here is his setup
For sale, CHEAP!

Hardware:
Atari 520ST with 4 Megabytes (includes RF to connect to TV)
Atari Mouse, of course
NEC double sided floppy drive (cable and power supply)
Avatex 2400 modem, with RS-232 Cable
OkiMate 20 (24 pin) color printer, with plug 'n' print and cable.
(with extra print-head, 100,000 character life)

Software:
WordUp 3.0
1st-Word
Tons of PD and Shareware programs on double sided floppy
ANSITerm 1.5b, DigiPlay Plus 1.5, ACC Manager
(pre-registered in your name; be sure to mention this)
STOS
Language Disk
Games Disk
Accessories Disk
Compiler
DEGAS (No manual)

Games (with manual and maybe box):
Star Trek The Rebel Universe (Both manuals)
Star Gider
Defender of the Crown
Barbarian
Ghost Busters Language

All for $690.00 (shipping not included)

GE mail to T.MILLER23

Source record: 42118

>I cannot seem to run Gemini and MiNT/TOSWin together. While Gemini is
[...]
>native. Is anyone running Gemini and MiNT together? Can it be done?

Yes. You must run your shell as TOSWIN-autostart program. That means, start Mintshel or whatever you use under TOSWIN and save the configuration. Then reboot.

Greetings, Hayo Schmidt

4150. Re: Cross Compiling Sozobon 2.0

Newsgroup: comp.sys.atari.st.tech
Date: 1992-10-31 22:48:15 UTC
From: dsb@duke.cs.duke.edu
Message-ID: <720571694@bronto.cs.duke.edu>
Source record: 42103

From the Holy Book of <1992Oct30.142436.28566@sol.ctr.columbia.edu>
as spake by richard@op.ph.ic.ac.uk (Richard Syratt) :
>OK people so why does sozobon ignore the 'long _initial_stack'
>declaration in mntlib's inistack.c. (It doesn't make it through to
>the lib)

Quite possibly because it wasn't in the Makefile; it is a new file.
Since I'm not "in the loop" with the rest of the MiNTlib beta-testers,
the HSC version usually has to play catch-up.

> And also, is it OK if I just change
>the 'extern long _initial_stack' in crtinit.c to 'long _initial_stack'.

I'd advise against it. The idea, presumably, is to allow the programmer
to say "long _initial_stack = REALLY_HUGE_STACK_SIZE;" in her program,
and have the library version kick in only if the programmer doesn't
define one. If you put the definition of _initial_stack in crtinit.c,
it will always be included and the programmer can't set her own value.

>Apparently this was changed for patch level 22, will my st have problems
>if I change this?

Be patient; I haven't had a lot of free time recently [being a full-time
grad student and working part-time technician will do that to ya :( ].
Having finally finished reorganizing my hard drive, I plan to break open
the sources and start on it tonight.

4152. Gem with Sozobon?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-01 00:14:14 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1992Nov1.001414.20452@oz.plymouth.edu>
Source record: 42104

Help!!!

I have Sozobon C for the ST and I'd really like to write some GEM
programs, windows and such so I don't have to switch out to TOS whenever I
run one of my programs, just a window to pop up. But, I don't seem to have
any libs to support such functions as would be needed to create windows, alert
boxes, and mouse control like form_alert(). So, are there and any out there
that can be added to my existing sozobon? Also, what happened to sfrttime()?
It is commented out in the #include file. Is GEM possible with sozobon,
or do I have to get another compiler? I do not have the memory to run GCC,
nor the disk space really.

Thanks,

Stephan

4153. Does Gulam screw up environmental variables?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-01 00:15:46 UTC
From: bgilbert@cs.washington.edu
Message-ID: <1992Nov1.001546.16859@beaver.cs.washington.edu>
Source record: 42106

Greeting to all you C programmers out there, I have a question for
people using Gulam as their shell :

Why does Gulam seem to put an "=" after every environmental variable
I type in (using the setenv command)? When my HSC 1.33 cc command tries
to compile the file, it screws up because the output file ends up
being "e:\=\hello.s" or something stupid like that. How can I get it
to stop putting the "=" in the PATH and TMP variables and all that? Or
do I need different version of CC?

Thanks in advance,

Yes, Sozobon C should come with the GEM/AES libraries which contain all the functions and things for accessing the windows/menus/dialog boxes, etc. (at least HSC comes with them). Look for the files vdifast.a, aesfast.a, or a similar name. And you probably need to include "gemfast.h" in your program to use the calls. Then, when you compile/link the program, be sure to tell the compiler to use the proper library -- usually by naming the .a file on the command line after your source file name.

Also, if you don't have any GEM documentation or anything, I'd suggest getting a book containing it, as it's kind of hard to figure out all the OS functions without docs... :-) C-manship by Clayton Walnum is supposed to be one of the best, and many dealers (Toad for example) carry lots of different books that would apply.

4155. DAMN DRIVE!! @!%$!@!!!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-01 01:13:04 UTC
From: wsbusr3@rw6.urc.tue.nl
Message-ID: <wsbusr3.720580384@rw6.urc.tue.nl>
Source record: 42108

Dear ST-HardwareBoys/Girls,

Weep with me:

All of a sudden my 1040ST-drive sticks its grey tongue out at me -
continuously !!
Usually it does that when a disk is inserted.
As you all know.
Upon hitting it, it spits the disk out, and swallows its tongue.
Old story. Until know. Obviously it decided to keep it out. In order
to get a disk in, I have to push it whilst inserting the disk !
I'd rather use my Xtra hand to hold a telephone or whatever.
Bah!!

Adding the fact that I didn't use it more forceful than usual
nor heard a CLICK, POINGNGNNG or CRACK,
and that I only molested it for four years now, I'd like to know:
- whether it can be fixed ?
- by a complete layman ?
- at low cost?

Personally, I never heard about such a silly malfunction before.
O well.
Now you all have. :(

Solutions / responses please to this group
to : at073@cleveland.freenet.edu

Thanx in advance,
Rowdy Blokland,
TUD,
The Netherlands.

4157. RTS/CTS flow control

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-01 10:17:40 UTC
From: wisner@netcom.com
Message-ID: <1992Nov1.101740.2599@netcom.com>
Source record: 42110

I'm attempting to set up my 1040ST and modem to use hardware flow control. It works, sort of; when the ST's receive buffer fills up, it drops the RTS signal as it's supposed to -- but then it doesn't raise RTS again until I type a character. Is this normal? Seems to me it should raise RTS as soon as the receive buffer's empty.

(UniTerm v2.0e, if it matters.)

m> know the TT is a bit slower at some things, maybe 25MHz 386dx
m> equivalent. I have no idea about the 68040 or the 486.

Hmm... I'm not too sure on that one - I use (& code for) a 386DX33 with a 387 at work, and my code seems (I say seems, I haven't timeed it) to run somewhat more snappily on my TT than the DX... and as a rule TOS seems to be a little quicker on drive/file operations.

However, there are a large number of other considerations here ... (screen I/O, genearl responsiveness, my bias, etc 8)

f> It's been a while since I last asked these questions and things might
f> have changed sufficiently to warrent asking them again. Please bear with
f> me.
f> 1. Is there an Ethernet board for ST/TT under TOS runing TCP/IP
f> protocol that is available in the US? Are the SCSI Ethernet boards for
f> the Macs workable on the ST/TT units? The service can be on demand
f> only.

Yes & no - there are a number of 3U ethernet boards available, and PAMsnet (from PAMsoft in, you guessed it, germany) supports at least one, providing TCP/LAT/IPX etc functionality. As far as I know, the SCSI ethernet devices are not yet supported.

f> 2. What tape backups are available for TT units? SCSI driver software?
f> PD? Shareware? What kind (Brand, model, and capacity) of mechanism?

I still recommend the ICD FAST units - at 155MB and >6M/minute they are highly performace-competitive, and work very well on the TT.

Alan Hourihane's TapeBios and port of GNU Tar also works quite well with a wide range of drives, however the driver requires a small patch to work properly on the TT, (Alan, have you fixed that yet??) and only talks to drives on the ACSI bus. (I would have fixed this, however my dev. kit still hasnot arrived (4 months and waiting))
(The patch is easily accomplished, I can provide details, or a fixed driver, if you like).

f> 3. What needs to be done in order to execute a program in TT fast RAM?
f> What tools are available?

Atari have released a program called PRGflags which allows these options to be set - the memory options for a program are contained in 3 bits in the header of the program.

f> 4. Is there a version of GFA BASIC that supports the math coprocessor
f> on an ST (as a peripheral device)? Is there one that supports the math
f> coprocessor on the TT? Will this run under the TT RAM?

At this point, no. Richter have recently acquired the rights to GFA basic (ST only) from GFA themselves, and are undertaking a complete rewrite, with the intention of completely legalising the package.

They may add this support - however I have no information either way.

f> Clarence Chang

This depends on a lot of things. IMHO, if I had enough memory, I'd run tcsh,
because it has a lot of really nice features.
But, I only have a meg, which is barely enough to do anything with any kind
of sophisticated shell, so I use something smaller, like the one that comes with
MiNT. However, with almost any shell, you're going to need a suite of file
utilities, and other utilities as well, and it is the choice of utilities that
will help define your environment. There are a few packages, such as the GNU
fileutils, the MiNT file utils, and the Alan Pratt utilities. You should try
them all out, and see which suits your needs most. There might be some others,
I'm not sure. You will need to get one of the packages to even do an 'ls' on
a directory, although, in a pinch, 'echo *' will do. But I digress.

4168. dragging a box and highlighting icons at the same time

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-02 09:22:31 UTC
From: mboom@mswe.dnet.ms.philips.nl
Message-ID: <1992Nov2.102231.131066@mswe.dnet.ms.philips.nl>
Source record: 42141

Hello everybody,

I am currently working on a programm which has a fancy user interface ala desktop. I am able to create a desktop with a dropdown menu, several icons on it and draw some windows and handle them successfully. Now what I want to do is to grab one or more icons and drag them to an other icon. That next icon should highlight when the mouse is on it.

I found some functions to drag a box and to highlight an icon when the mouse is on top of it, but I can not figure out how to combine them. Is the only solution really to handle the complete drawing of the box and icons myself, or is there another way?

Any help please,
Thanx,

Marcel.

4169. Help: ICD with Miniscribe

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-02 11:34:13 UTC
From: ari@fwi.uva.nl
Message-ID: <1992Nov2.113413.9123@fwi.uva.nl>
Source record: 42130
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello fellow-Atarians,

Has somebody tried to connect a Miniscribe 8425S to a ST1040stfm ?
I tried it and used on old ICD host adapter (with built in Clock).
The partnumber of the adapter is 9010 (year 1987).

First i tried the diskdrive with an Apple Macintosh+ computer, it worked
ok.
But when i try it with my Atari and hostadapter, it doesn't see the
diskdrive (No disc connected), when i use the format-program that
belongs to the host-adapter. One can even select the 8425S diskdrive,
it is one of the standard formats. It keeps saying "No disc connected".
The terminating of the SCSI and the power-supplies are ok, they are
tested with the Macintosh. I can even read the onboard clock with
an ICD utility.

The hostadapter has also been tried with a (Macintosh formatted)
Quantum 52 LPS diskdrive, it didn't see that diskdrive too.

The next i tried, was to use the hostadapter with somebody else's
ST1040 and diskdrive (I am not sure what diskdrive it was, SH204, i
thought it was a Seagate). The system booted, but of course with
an already formatted diskdrive but not with the Miniscribe. It showed
that the hostadapter was ok (?).

On the Miniscribe diskdrive one can intall 6 jumpers, the SCSCI-id
jumpers (the three nearest to the connector) are empty. So it
should be on ID = 0 (the Macintosh says so too).
The fifth post is jumpered (auto-parc ?).

What do i forget? Is there somebody, who can help me with this problem ?

Thanks in advance,

Arie Maaskant.

Is Atari dying.... ?

Not at all. The Posting you have is a FAKE !!! Do not distribute stuff like this. Some Hacker entered the german MAUS net and posted it. There was a long discussion about it, but in the end it turned out to be complete nonsense !

Walter

>groups could be made international I would love to see that happen.

As far as I know we had shortly ago a request from somewhere in the states
if it would be okay to make the groups (at uunet?) available. As we didn't
deny that (in fact we wrote back that it's OK with us ;-)) i guess the groups
should be available somewhere there.
The only problems seem to be, where to get the groups and how to pursuade
the local newsadmin to get them. ;-)

4172. time.h with gcc?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-02 13:20:41 UTC
From: lahtinen@gideon.fmi.fi
Message-ID: <lahtinen.720710441@gideon>
Source record: 42121

I am starting to use gcc and made some simple test programs.
I noticed that when I included "time.h" I started to get error
message. I am not now at home so I do not remember the actual
message, but it was on line 71 and something about empty something.
I am using include80.

By the way I am using MultiGem II and it is nice program, but
I would like to know is there a shell (cli) that I could use
with it?

Source record: 42120

Recall I was having problems with nm and ld compiled on a sun???
Well I was.

Anyway, the problem with nm was a bug...
to fix this, change line 185ish of nm.c from

```
if (reuse)
```

to

```
if (reuse || xhave == -1)
```

then it works fine.

The problem with ld was also a bug :-) (happy because it's not
me that got it wrong)

The linker couldn't find __initial_stack in the library - I've discovered
this is because of a naff hash number creation routine. __initia...
and __init_s... both give the same hash number - so the __initial_stack
entry gets replaced :-(

I can't mess about with it anymore today, but I'd appreciate it if someone
could post/send me a better hash routine (here's the included one...)

```
hash(s)
unsigned char *s;
{
unsigned char c;
register i, n = 0;

for (i=1; i<5; i++) {
c = s[i];
if (!c)
break;
n = (n<<1)|c;
}
return n & (NHASH-1); /* NHASH is the max value */
}
```

I've spotted that this routine only uses the 1st to fifth letters of
the name (skipping the first underscore), and that this is the same
for both __initial_stack and __init_signal, but increasing the number
doesn't help - in fact the routine only seems to return hash values
of 46,61,62,63 whatever is passed through to it when it uses seven
characters.

Well I think this is the problem - flame me if it's not...

Richard

Message-ID: <1992Nov2.145045.26133@news.cs.indiana.edu>
Source record: 42122

I have inherited our assembly language/architecture course along with a room full of ST1040's used in the lab portion. They are a nice platform and perfectly adequate in this application.

We are exploring building our own versions using PC clone peripherals to keep costs down. We are experienced users of field programmable gate arrays and would use them to replace the GLUE, MMU, SHIFTER, and DMA chips in the ST. If they are simple enough I might even assign some of them as projects in a VLSI class although the partitioning would likely be different because of pin limitations.

We have printed circuit CAD software and would use it to build an open system mother board with connectors for peripherals. Form factor would be compatible with a clone case/power supply since they are ridicuously cheap.

Anyone know the nitty gritty internals of these chips? I really don't want to reverse engineer them with a logic analyzer.

In the Atari ST Internals book, pp13, the prototype ST using TTL chips is mentioned. Were circuit diagrams of this ever circulated?

I am new to this group. Can anyone guide me to reference sources. I have the ST internals book and the ST logic diagrams.

Source record: 42123

Hi,

As a person who has spent the last ten years programming almost solely
in BASIC, the ins and outs of memory management are fairly new to me.
I'm currently trying to write a program which needs to know where it is
in memory. My GEMDOS information tells me that the 'C' call getmpb should
do this - but it seems to return only the top of system memory or something -
it gives the same thing every time with no pointer to a second block.

Am I being very thick or is there some other way to find out my program's
basepage? I'm running an STe with 2Mb of memory and TOS 1.62.

Thanks - and apologies if this is a silly question!

Keith.

I've used one of the 84xx Miniscribes on the ST, and it worked fine.
My first suspician would be that the drive is set up with parity enabled
for a dos clone. I'm not sure, but that might be what the other jumper
does. Try removing it.

>The hostadapter has also been tried with a (Macintosh formatted)
>Quantum 52 LPS diskdrive, it didn't see that diskdrive too.

Old ICD host adapters can't talk to Quantum drives. They don't
recognise the extended command set. You have to get an adscsii pro

I never thought that this nonsense mail in our little MausNet would get through the world like this. I am a Sysop of the Maus ST, that node of the MausNet, in which the Mail appered the first time and I want to assure you,

that this mail is DEFINITLY NOT from Alwin Stumpf (former general manager of Atari Germany) and I hope that the editors of AEO will read this before they print this nonsense once again like STReport did.

All listed facts aren't facts. They are all born in a very small mind in a phase of thoughtlessness, as other users of our MausNet already pointed out, even in the FidoNet where STreports got this mail.

I don't know, how often I red this mail again and again in the last few days in the different newsgroups and nets.
But I think this mail got in a vakuum of information deficit and because of this, so many Atari enthusiasts thought to read a real statement.

I hope this will end this discussion about this dummy mail.

Nevertheless, if someone is still interested in german newsgroups of the MausNet, you can get them under the name maus.sys.atari.* on a mailserver in the States. Some weeks ago somebody posted here, that he could get them there, but I don't even know where exactly.

By the way - why is it so difficult to mail from InterNet into Genie? I tried to connect Dragonware and Fast Technologie but can't get through :-(. Aren't they interested???

Tschau... Ralf

This seems like a misconception to me. The purpose of a hash function is
to project a huge area (here the name space of all acceptable symbol names)
into a much smaller area, the hash table held in computer memory. It is
therefore quite necessary that different input values (symbol names) map
to the same hash value, although one would try to reduce the probability of
such clashes to a minimum. This minimum probability is related to the size
ratio of source and destination areas and is certainly not zero. What is
obviously broken is the code that uses the hash value to place or locate
names in the hash table. It must be able to handle name clashes sensibly,
of which there are several possibilities. (See Knuth's "Art of Programming"
for a detailed discussion, I'll only mention two approaches: either scan
the hash table for an empty slot, or use linked lists for names with
identical hash values. In either case, the hash table has to store the
name for later comparison, the original code at your hand may be naive
enough not to do that.

```
> hash(s)

>
One might argue over the sensibility of a hash function that only looks at the first characters of a name. It is often a bad approach because some programmers enumerate their variables (like file1, file2,...; not recommended), others use a verb-object template for their function names (get_this(), get_that(), get_next()...). Nevertheless, a bad hash function only slows down the calling code because it has to do more work to solve the name clash.

> Well I think this is the problem - flame me if it's not...
Na, me never does this!

I do not know about this particular topic, but most of gcc documentation
is written with Texinfo macro package. "For those who don't have TeX"
(and for those who have, but want/need another display format) tools
for dealing with such files - texinfo package - were posted in
comp.sys.atari.st.{sources, binaries}, on atari.archive.umich.edu
(unfortunately in TeX directory) and are also mentioned in FAQ.
Not counting annoucements in comp.sys.atari groups.

Everyone knows Atari will not stop production on the Falcon, that would be rediculous. Even the local PAPER has a run up about the Falcon, and for Atari, that's AMAZING... Most people around here don't even know what an Atari is... aside from a 2600 game machine. All you ever see is IBM & MAC. I was very impressed to see the falcon gaining in popularity. I have also seen a company in Britain (in ST format) claiming to sell the FALCON.

The Maus newsgroups are e.g. available from the nntp host
news.rus.uni-stuttgart.de. (Usual disclaimers apply.)
They are somewhat different from Usenet newsgroups, though.
First, they are entirely in German; second, since the Maus Net
somehow connects the messages, older postings are
seldom quoted.

Have fun, Cornelius (Internet-User & MausNet reader).

4189. Falcon BUS..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-04 12:44:17 UTC
From: mpnolan@unix1.tcd.ie
Message-ID: <mpnolan.720881057@unix1.tcd.ie>
Source record: 42140

I believe that Atari have at last got their act together...

Q: As the Falcon has (from what I've heard) one bus (32),
how will the custom chips (DSP,DMA Sound,Blitter,H-Scrolling,..)
interact, and will the system lose preformance as a result?

Surely the DSP has it's own bus, as it does have 56k of it's own
memory!?

You can always tell how good a machine is by observing how
defencive amiga owners get...and believe me, I've never seen
them so bad...!

Please dont spare me on the technical info., I'd love to hear it
(I'm sure I could understand it - I study Comp. Sci.)

Thanks, Mark Nolan

This is true. I have been meaning to post something about this myself. Basically graphically intensive operations will slow the processor down considerably. This is also the situation on the Amiga. However, the Amiga also has "fast" memory, which the processor cannot access. A system with fast memory will have substantially improved performance. If the Falcon has no provision for "fast" memory, then those Amiga owners who claim that the A1200 is faster could well prove right :(

The benchmarks posted to the Amiga groups indicated that an A1200 with no fast memory was only about twice as fast as an A500. Before you start smiling though, it still proved faster than an A3000 without fast memory. A3000's with fast memory are *very* much faster.

>Surely the DSP has it's own bus, as it does have 56k of it's own
>memory!?

Hmm. Don't know much about the DSP. Anyone else care to comment.

>You can always tell how good a machine is by observing how
>defencive amiga owners get...and believe me, I've never seen
>them so bad...!

Grow up. The Falcon is good (very good in fact) but it is not that good. In the UK at least the A1200's pricing and specification make it an excellent home computer. The Falcons' pricing places it dangerously close to the serious PC market. The A1200 might not be as good as the Falcon, but at the price I'm afraid to say it will become *the* home computer over here.

Sorry about the "grow up" bit, but for as long as I can remember people always seem to want to prove their computer is better. This went on through the C64 and Spectrum era, was continued by the Amiga and ST and looks set to continue with the Falcon and A1200. Personally, I'm more than a little tired of it.

Incidentally, if you think Amiga owners are defensive, try insulting the Falcon in one of the Atari groups :)

I use a SM146 with a Mega STE and hear keyboard clicks & music etc. with no problems. The SM146 has a volume control and speaker, just like the SM124 & SM125.

Does anyone have a better story as to the differences between the SM144 and the SM146?

According to Atari the Falcons memory runs at 0 wait states. Thats as
fast as memory can run folks. What Atari has not stated was whether the
Falcon uses a syncronous, or asyncronous bus. If the bus is syncronous
the CPU can have data from memory within 90ns of requesting it. If the
bus is asyncronous then the cpu can have the data within 120ns of
requesting it. Regardless of which access scheme is used a wait state
will be 62.5 nano-seconds.

>setenv BUFSIZE 4096
>==========cut here==================
```

>Hope this helps... I think the solution is in using 'set' for the path...

Gulam didn't use environmentvariables. All environmentvariables you set
with `setenv' will only be given to the processes started from inside of
gulam. If you wants to set variables which gulam should use you have to
set them with `set' and write them lower case. There are several shell
variables you can set for gulam. I didn't have a list of the shell variables
which gulam understands by hand. Look into the manual.

Hope that helps,
Alf

4196. Problems using Fast-RAM on the TT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-05 03:01:46 UTC
From: dc@presto.ruhr.de
Message-ID: <7664648@presto.ruhr.de>
Source record: 42148
Cross-posted to: comp.sys.atari.st.tech,de.comp.sys.st

I'm having problems using the TT Fast-RAM particularly in combination with MiNT (0.95). The configuration is TT, TOS 3.06, 4MB ST-RAM, 4MB TT-RAM, AHDI 6.01, 200MB Quantum HD.

Without MiNT most larger programs (e.g jwb's GCC 2.2.2 port or GNU-Emacs 18.58) crash if the header-bit is set are so that they run in Fast-RAM (in ST-RAM they run fine).

With MiNT _any_ program that writes to a location beyond about 1MB into the TT-RAM crashes the system completely. Just clearing the fast-bit in the header so the program tries to clear the TPA is enough to cause this, even if the program itself doesn't write anything to memory. Reading from TT-RAM works, and writing back exactly the same data that was read also works. So it looks like something is using memory that it doesn't own.
If I boot MiNT from floppy with no HD driver everything seems to be OK, which would seem to indicate that the combination of MiNT and AHDI is the problem - except that other people (including Eric Smith) are using the same configuration and don't have these problems.
The result of this is that only about 1MB of the TT-RAM is useable.

This could be a hardware problem, although it's almost certainly not a bad RAM chip since TOS 3.06 does a memory test when it cold boots, and it says everything is ok. The other possibilities are bugs in TOS, MiNT or AHDI.

Does anyone else have a similar setup and know what might be causing the trouble? If it _is_ the hardware, what is it likely to be?

Answers via email would be preferred - if anyone else is interested I can send them a summary.

I think you're confusing RAM size with the name of the chip. It's a Motorola
56001 chip, or 56k short. It's got 96k of private static RAM and I think the
bus is going in parallell to the CPU, with an own bus to the 96k of RAM, of
course.

Please correct me...

Message-ID: <1992Nov5.114927.14711@dcs.warwick.ac.uk>
Source record: 42154

I asked questions similar to these a month or two ago, but nobody answered. Perhaps somebody knows the answers now.

1) What is the speed of the Falcon's memory (Somebody said it had 0 wait states which seems to imply 16MHz, but they may have been wrong)
2) How does the DSP access the main memory (Somebody said it is not connected to the data bus, in which case I suppose it must be some kind of serial link)
3) Does the TOS V4 use the DSP to speed up things (for that matter does it make intellegent use of the Blitter?)
4) Is the data bus between the memory and the 68030 16 or 32 bits wide (There seems to be an argument going on about this).
5) Why does the benchmarks that I have seen posted here only indicate an approx 3x speed increase and real-world tests (excluding any disk access) only twice as fast? If the data bus is twice as wide, the memory twice as fast, the processor at least twice as efficent and running at twice the clock speed it should be more like 10 times the speed.

Thanks,
Leo

4202. pds slot specs wanted

Newsgroup: comp.sys.atari.st.tech

> 1) What is the speed of the Falcon's memory (Somebody said it had 0 wait
> states which seems to imply 16MHz, but they may have been wrong)

The memory, as I said, is claimed to be 0 wait state memory. The question
is is the memory syncronous or asyncronous?

> 4) Is the data bus between the memory and the 68030 16 or 32 bits wide (There
> seems to be an argument going on about this).

Atari claims 32 bit wide memory.

> 5) Why does the benchmarks that I have seen posted here only indicate an
> approx 3x speed increase and real-world tests (excluding any disk access)
> only twice as fast? If the data bus is twice as wide, the memory twice as
> fast, the processor at least twice as efficent and running at twice the clock
> speed it should be more like 10 times the speed.

My best guess is that when people get to the Falcon in the REAL world
they increase the number of bits per pixel, causing a lot of extra time
to be spent drawing things, like letters and numbers. You will pay a big
price in performance for more bits per pixel on Atari systems. Refer to
the description of pixel memory in either the developer docs or the Abacus
internals guide.

On an unrelated topic...

Yesterday I said would see if you could drag a HD icon to a floppy icon
under NeoDesk. The answer is yes. NeoDesk informs you that it can only
perform a file copy, sector copy is not available. I do not have access
to a floptical so I can not verify if NeoDesk will recognize that a 720K
or 1.4meg floppy in a floptical has the same format as it does in a
standard floppy drive.

|> > doesn't help - in fact the routine only seems to return hash values
|> > of 46,61,62,63 whatever is passed through to it when it uses seven
|> > characters.

This is a truly _awful_ hash function; simply ORing and shifting is
going to produce a heavy bias towards hash values with lots of ones -
especially in the more significant bits:
46=%101110, 61=%111101, 62=%111110, 63=%111111
(one can guess that NHASH=64)

Replace the OR (|) with addition (+) or exclusive-OR (^) for some improvement.

|> >

Agreed. I believe the Sozobug loader only deals the first 8 characters
of a name so I'd hash on 1 thu 7 (starting at zero!);
i.e. replace the 5 with an 8 in the above code.

Steven

4205. How to become an Atari developer

>1) What is the speed of the Falcon's memory (Somebody said it had 0 wait
>states which seems to imply 16MHz, but they may have been wrong)

I'm not sure, but doesn't it have to be 16 MHz if it is on the same bus? I should know this because I had a computer architecture class last quarter, but they didn't go into specific implementations. Or do you mean to ask about the access time (such as 120 ns, 80 ns, etc)? This might be a more interesting detail.

>2) How does the DSP access the main memory (Somebody said it is not connected
>to the data bus, in which case I suppose it must be some kind of serial link)

Don't know on this one, but I think you're right in that it's not connected to the data bus. I guess the link must be sufficient if the Falcon can grab true-color off the hard disk at 24 frames per second and display it in real time. :-) Although maybe they didn't use the DSP for that...

>3) Does the TOS V4 use the DSP to speed up things (for that matter does it
>make intellegent use of the Blitter?)

The DSP is not used by the operating system unless you call it. The SDMA sound engine handles all the sound processing, meaning playing 16-bit 50KHz digitized sound can happen with no CPU loading, so that's one thing you won't have to worry about. The BLiTTER has been combined with a bunch of other things on a single chip, and it now runs at 16 MHz. The BLiTTER is also used to feed the SCSI port DMA in order to speed up hard disk access. I imagine this helps a lot when doing direct-to-disk audio or direct-from-disk audio/video (as in the Tina Turner video thing). One more thing : the DSP operates at 32 MHz and is rated at 16 MIPS.

>4) Is the data bus between the memory and the 68030 16 or 32 bits wide (There
>seems to be an argument going on about this).

The Falcon030 has a 32-bit data bus and a 32-bit address bus. This _is_ a 32-bit computer, folks.

>5) Why does the benchmarks that I have seen posted here only indicate an
>approx 3x speed increase and real-world tests (excluding any disk access)
>only twice as fast? If the data bus is twice as wide, the memory twice as
>fast, the processor at least twice as efficent and running at twice the clock
>speed it should be more like 10 times the speed.

>

Ok, some of those points are debatable :
1) Yes, the data bus is twice as wide which overall should provide
a doubling of effective throughput.
2) The memory twice as fast? I don't know if this is true at all --
perhaps someone else can confirm/deny this. I really haven't
seen any details about the speed/configuration of the RAM.
3) The processor is twice as efficient? Are you sure about this?
We all know the 68030 is a newer chip, presumably making it a
better design (and it also has more stuff, such as the MMU and
on-chip instruction and data caches), but you seem to be saying
the 68030 can execute the same code as the 68000 but in half the
number of cycles. Frankly, I doubt this.
4) Twice the clock speed is right, definitely. That one's not
too hard to figure out. :-)

So, the way I see it, we'll have about a 4-5x speed increase, and maybe
more with heavy use of the co-processors (BLiTTER, DSP, SDMA), some of
which aren't even available on the ST or STe.
Also, remember the Falcon video modes require up to two bytes per pixel,
which in 640x400 is 512K of screen memory to wade through. On a positive
note, though, there have been reports saying that the Falcon's 640x480x256
mode appears as fast as the TT's 640x480x16 mode, which really is pretty
snappy, especially with Warp 9 installed.

Excuse me, but where did you get that from? Sam Tramiel stated in the GEnie conference a long time ago that it has a 32-bit bus. Also, somebody tested Falcon with QIndex and got 471% for the CPU memory test, compared to a normal ST. I don't see how this could be possible with a 16-bit bus. So please tell me (us) where this information came from?

That is the "less" that I am using, but I am using tcsh right now.
I'm still having MiNT problems so I haven't been able to test whether it
has those same problems.

4209. MiNT, TCSH, CoNnect, Warp9...what they have in common?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-06 07:51:18 UTC
From: mbaffoni@skat.usc.edu
Message-ID: <1dd85mINNlra@skat.usc.edu>
Source record: 42163

My journey in search of a system with MiNT, TCSH, Warp9, and CoNnect working very happily together has been a long one with both ups and downs, and strange sights indeed! Let me exemplify:

When I load _just_ MiNT and TOSwin(1.1), I am completely, utterly unable to run another GEM program - PID errors and such.

If I load _just_ MiNT and TOSwin and have something "INIT="ed, it says "leaving MiNT" just before it drops me into the desktop, nothing running, and every .acc except TOSwin is loaded. I can't run .prgs.

If I load Warp9 (as well as all the rest of my junk), MiNT, TOSwin, Warp9.acc, then everything has the new font, but I still can't run any .prgs. Warp9.acc is accessible, no bombs.

If I load Warp9 (as well as all the rest of my junk), MiNT, TOSwin, Warp9.acc and have ConNect set to autorun (from the inst app of GEM), it runs at bootup, just like it should, Warp9 is active, MiNT and TOSwin are active, and I have no problems whatsoever accessing the Warp9.acc. In fact I can quit CoNnect, it puts me at the desktop, I can run most of my .prgs (including the old, original First Word!) and both Warp9 and TOSwin accs are accessible. No bombs. This would be idyllic....EXCEPT EVERY ONCE IN A WHILE IT SEMI-LOCKS UP!
This lockup behavior occurs whether I have just MiNT and TOSwin or whether I have Warp9 and the kitchen sink thrown in (but never when MiNT isn't loaded). What happens is whatever was happening stops. Sometimes I can use the mouse (it moves as per normal) but it can't _do_ anything. Menus aren't selected, window boxes can't be pressed/highlighted. Keyboard at this time _definately_ does not work. The only way I have found to stop the lock is to warm boot. Has anyone _ever_ had MiNT lock up like this? Is this not a real Lockup, but rather is some process that is stealing all the CPU cycles except what is used for the mouse handler? Remember, this is with _or_ without warp9 so that shouldn't have anything to do with it. Oh, if it makes any difference, when I _do_ have Warp9 and everything else loaded, the lockup occurs more often - I can do it every time, by dialing in from Connect. As soon as the modems connect with each other, it locks up.

If _anyone_ can help me with this, I would _greatly_ appreciate it.

Thanks in advance,

MikeB

The truth is: the F 030 has a internal RAM port with 16 data and 24 address pins. (i've seen the specs and I've seen the layout)

On the other hand a german magazine has tested, that the processor accesses the RAM as if it was a 32 bit memory.

If the second statement is true: are they multiplexing?

|>

OK I agree the hash function needs changing, but... I've decided it's not
the problem ... but I'll change it anyway. After a while running ld through
a source level debugger to try and work out what it's doing I've discovered
what's going on and managed to recreate the problem... half way there now at
least.

ld will not pick up *any* externally defined uninitialised variable from a
library! Would some one like to check if hsc fails with this?

e.g.
test.c:
int test_var;

cc -c test.c
ar r test.a test.o

test2.c:
extern int test_var;
main()
{
test_var=3;
}
```

cc test2.c test.o works
cc test2.c test.a doesn't!!! (undefined symbol _test_var from test2.o)

nm reckons they contain the same info - so I'm now checking
out the differences between how ld handles an object file and a library.

[stuff deleted]

|> Steven

Richard

BTW anyone know if sozobon can be emailed, and if so where?

4213. Compiling mintlib with a bug ridden Sozobon2 (was: Re: Cross Compiling Sozobon 2.0)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-06 11:49:19 UTC
From: richard@star.ic.ac.uk
Message-ID: <1992Nov6.114919.28271@sol.ctr.columbia.edu>
Source record: 42170

If you've ben following this then you'll know I was having problems with
the sozobon 2.0 link editor (ld). I *think* it's finally sorted out...

ld was failing to pick up uninitialised variables from a library, definitely
a bug. I believe this can be fixed by changing line 297 of syms.c (ld source).
It was something like:

```
if (sp->flags == EXTREF || sp->flags == COMMDEF)
```

This is definitely wrong, since there are other bits of code whcih check
for COMMDEF which can never be reached as things stand.

change it to:

```
if (sp->flags == EXTREF)
```

Although this might not be the answer, it works as far as I can tell,
(why was it there in the first place???) but since I'm cross compiling, I
havn't actually checked to see if the executable actaully is. (executable).
Can't see why not though.

Still on the subject of bugs in sozobon2, nm needs a fix,
the easiest thing to do is change tools/nm.c in subroutine dosym
(about line 185):

```
...
int n;

if (havex == -1) <-- add these
reuse = 0; <-- two lines
if (reuse)
reuse = 0;
else {
...
```

Do I have to use snail mail (even when it does go by air) to contact sozobon?

Hope this is actually useful to someone... Scott?

Other things you need to do to get mintlib compiled are:

- Apply the relevant patches found with the current sozobon mint libraries.
some of these are no longer necessary.
- Change patchlev.h so that it uses ' instead of " for the #define bits -
(another problem with sozobon ...), and change the ~ in ident.c to
' as well.
- In files such as fscanf.c there are typedefs that sozobon doesn't like,
I think you can delete these and any references to the things they

were defining ... parameter passing defaults to type int doesn't it?

I think that's it - there's probably a few warnings you might like
to fix (uncast mallocs etc).

I'll test it over the weekend, probably find I've got it all wrong :-(

>>setenv BUFSIZE 4096
>>==========cut here==================
>
> stuff deleted
>
>
Don't get me wrong, I like Gulam a lot and use it daily and the
above discussion on environmental variables has been adequately covered.

BUT - my one persistent and remaining gripe against GULAM is in
its definition of $cwd

IF $cwd is the root directory of a volume/partition (e.g. A) then
Gulam sets $cwd as A:\ (i.e. WITH a trailing backslash)

However if we are in a sub-directory (e.g. C:\SRC) then Gulam sets
$cwd as C:\BIN (i.e. WITHOUT a trailing backslash )

This causes hell with my $-aliases for C and FORTRAN compilations
etc. which, ideally, I would like to configure so that I could compile and
link a file in ANY directory - be it a ROOT directory or otherwise.

I can see no logical reason for this choice by the (very worthy)
originators of Gulam ( Messrs. Mateti, Bammi et al.). Indeed other shells
(like CRAFT) don't do this - but I dislike CRAFT as it does not support
$-aliases and is rather big (compared to GULAM) with no built-in editior.

I wonder if anyone out there knows better - or can advice me how
I may in Gulam get it to define $cwd as A: and NOT A:\ .

Cheers, W. Alan B. Evans

What do you mean by this? It is my understanding of the 68k that the bus has always been asynchronous -- there is no fixed slot in the bus timing for reading or writing. The processor simply waits until the data has been transferred, when the peripheral asserts various lines to inform the 68k that it's finished.

Do you mean burst mode, used for cache filling?

>My best guess is that when people get to the Falcon in the REAL world

>interact, and will the system lose preformance as a result?

It has ever been the case that the CPU must stall when DMA is taking place. The DMA chip grabs the bus for a short time and does a block transfer (if I remember correctly, the block size is 16 words for the ST's DMA transfers -- it may have changed for the TT / Falcon). During this time, the 68k has to wait until the bus is released.

The video system in the ST was designed so that processor access and video shifter access are interleaved. On the original ST, the memory subsytem runs at 16MHz, so that processor (8MHz) and video access can be interleaved. It's a bit more complicated than this (we had the discussion some months ago, and I forget the exact details -- sorry). Horizontal scrolling is simply some extra logic in the shifter and has a minimal performance penalty (you need one extra memory access at the end of a line).

>Surely the DSP has it's own bus, as it does have 56k of it's own
>memory!?

The DSP is a member of the Motorola 56k series -- it has 96K of static RAM. The DSP has its own data and address buses, independent of the 68k address and data buses. I don't know how the DSP and 68K communicate, but I would guess that there's some sort of shared memory scheme (but that is just *my guess*)

Does anybody know where I can get a 14pin connector for the external
floppy on a 1040STfm? (Preferably in OZ or mail order...)

These next bits must be FAQ, but I don't know where the FAQ is :(

1. What happens if I plug a 1.44M floppy drive in? I assume it will
behave as a 720k. Is there an easy way to get a 1.44 recognized?
(Like a new bios?)
2. What adapters exist for MFM and IDE drives, how much do they cost
(again pref in OZ) etc.

Please reply by email, and cc to 9107373@zeppo.cs.su.oz.au as my account
may die...

Thanks

If you specify an INIT in your MINT.CNF file then it ordinarily will not
make it to the GEM desktop, so TOSwin is irrelevant then. The "leaving MiNT"
message means your INIT program exited, so MiNT shuts down. TOSwin is
absent from the resulting desktop because it only installs itself if MiNT
is active.
>

Strange. Warp9.acc almost always caused a lockup for me. I've only installed
the patch for 3.71 tho, I'm not up to the current (3.73?) yet.

I've noticed that the Warp9 screen saver tends to lock up my MiNT sessions.
I haven't figured out how to disable the screen saver yet.

I also have problems with a lot of programs when BIOSBUFfering is active.
Uniterm exits with a bus error when it detects the CONNECT string after
auto-dialing a number. Big pain, haven't been able to track it.

>I'm not sure, but doesn't it have to be 16 MHz if it is on the same bus?

Not really. How do you think they get memory to work for 25MHz+
machines? Its not because they use 20ns memory (which is just cache ram)
but rather because their memory controllers insert "wait-states" to handle
slower memory.

>I should know this because I had a computer architecture class last
>quarter, but they didn't go into specific implementations.

Bum class. You'd think they'd go into basic memory handling....

>>2) How does the DSP access the main memory (Somebody said it is not connected

The Falcon's DSP is integrated with the SDMA hardware. Just from the
name, I'd hazzard the guess that the SDMA chips DMA information directly from
memory (or wherever) and place it on the private DSP bus (or more likely into
the DSP's 96k memory). Since it is DMA, it is not likely to be a serial link
(EEEWwwwww!) but a full blown 32-bit data path. The only serial data I know
about is the DSP connector is a high-speed serial connection (from what I hear,
its around 1MB/s!).

Well, my estimate of TT speed is as compared to 32-bit Unix on a 386dx.
Under DOS, you're looking at the TT being somewhat faster - not to
mention more capable. OS/2.0 would be faster, except for that silly PC
video bus crippling it.

Right, but once it can't/isn't loading the program that is to be INITed
shouldn't it reinstate MiNT and therefore TOSwin? Besides, are there
limitations on what can and can't be INITed? Like is it a bad idea to INIT a
GEM program? If not, then why is it not running say CoNnect from the INIT=
when it works perfectly fine from the desktop?

>I haven't figured out how to disable the screen saver yet.

I thought about that, but I turned the screensaver off (since I had
access to it) and it didn't help. BTW, why don't you just put "scrnsave.off"
in your warp9.dat file and it will turn it off for the entire session, or
configure your warp9.dat file so that it shuts the screensaver off whenever
you run a program that has problems with it?

>I also have problems with a lot of programs when BIOSBUFfering is active.
>Uniterm exits with a bus error when it detects the CONNECT string after
>auto-dialing a number. Big pain, haven't been able to track it.

You know something, I can 100% gurantee a lockup whenever I get a
Connect message from the modem, regardless of whether I am in the dial
menu or whether I am in the "direct" terminal. In fact, I believe I remember
ctl-alt-deling while connected, and it being frozen before I could do anything
(which is unusual since it usually takes some action on my part before
something crashes). I wonder if just being actively connected to the modem
has anything to do with it....

You don't say what host adapter you are using, also what type of DMA chip that was fitted, is it the 1991 version..

Early SUPRA host adapters will not work on a STE....

4223. Quantum 105LPS on ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-07 18:33:26 UTC
From: jeffy@syrinx.umd.edu
Message-ID: <16876@umd5.umd.edu>
Source record: 42178
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I'm trying to get a Quantum 105LPS to work on my Atari ST. It's an original 520 with TOS 1.0. I'm using a Supra Host Adaptor (one of the early ones, from ~'88, before the clock chip and DMA passthrough were added). Software is Supra 4.03, from 1990. I've got my original ST138N Seagate drive set for SCSI 0. The computer would not recognize the Quantum at 0 or 1 (0, obviously, was tried with the Seagate out of the system). The drive will boot and supposedly format at SCSI ID 4, but data is not being written correctly to the Quantum.

In addition to the 3 jumpers for ID select, there are 3 other jumpers, labeled SS, EP, and WS. As the drive did not come with a manual, I have no idea what these are for. With EP set, the drive is not recognized. With SS set, the drive went into a continuous seek and was not recognized. With WS, the drive would not power up at all.

Has anybody gotten the Quantum to work correctly with the Supra H/A? Is there something obvious I've missed here?

Any help would be appreciated.

Jeff

My personal opinion is dump the Supra and get an ICD. But then I'm
not the one who needs to shell out the money... :).

>In addition to the 3 jumpers for ID select, there are 3 other jumpers,
>labeled SS, EP, and WS. As the drive did not come with a manual, I
>have no idea what these are for. With EP set, the drive is not recognized.
>With SS set, the drive went into a continuous seek and was not recognized.
>With WS, the drive would not power up at all.

Don't put any jumpers on SS, EP, or WS. SS is Self Seek - its a test
mode that the factories use to test the stepping mechanism of the drives
(or so I have been told - I still don't understand what significant data
can come from this test other than the heads move - not that they go to the
right track, or experience track drift, just that they move. <shrug>). EP
is Enable Parity. Don't use this as the atari does not use parity for its
I/O streams (well, at least none of the host adapters I know of do). WS
is Wait to Spin. Basically it is an option that makes the drive wait to spin
up until it is "woken" up by an appropriate "wake up" signal from the SCSI
bus. I think some Macs may have this capability (but I have never known
a Mac (let alone any other computer, except maybe an XT :) that you would
actually want to start the drive wakeup _after_ you start the machine as it
generally takes longer for the drive to reach speed and initialize than it
takes most machines to do their memory check and request info from the HD).

Look, if the drive doesn't work at ID=0, in all likely hood it will
not work with that setup. I believe the ID=4 is a fluke. Good luck anyway.

Better get in touch with Supra. I know when I got my 52lps, my old
ICD host adapter, even with the rom ugrade, wouldn't work with the lps. I
ended up having to buy an ADscsi pro. I think the lps uses some of the
newer scsi commands that these old boards don't understand.

> reading or writing. The processor simply waits until the data has been
> transferred, when the peripheral asserts various lines to inform the 68k
> that it's finished.

> Do you mean burst mode, used for cache filling?

The 68030 supports two memory access methods syncronous, and asyncronous.
The memory controller uses a signal to inform the 68030 which type of
memory access it will support.

Syncronous memory accesses require 4 timing states to complete the access,
while asyncronous memory accesses require 6 timing states. At 16 Mhz a
timing state is 31.25 nanoseconds. Therefore using syncronous memory accesses
the CPU can accesses memory every 125 nanoseconds, while using asyncronous
memory accesses the CPU can access memory every 187.5 nanoseconds.

The 68030 instruction cache is filled by the CPU recognizing processor
states that will not access memory and will perform a memory read in advance
based on the program counter. The 68030 data cache is filled only on reads
to data space and they can not be anticipated.

I am not sure how Atari has implemented Burst Mode on the TT, but a typcial
implementation with nibble-mode-ram is as follows:
1) On first access perform normal memory access, syncronous or asyncronous
memory access with as many wait states as needed.
2) On subsequent accesses, if they are sequential, remove the proper
number of wait states, and possible switch to syncronous access.
This is actually implemented in the memory controller not the CPU.

> >My best guess is that when people get to the Falcon in the REAL world

> >to be spent drawing things, like letters and numbers. You will pay a big
> >price in performance for more bits per pixel on Atari systems. Refer to
> >the description of pixel memory in either the developer docs or the Abacus
> >internals guide.

> Please elaborate -- why do we pay for more bits per pixel on Atari systems?

Video memory consists of some number of bit planes. The video memory designer
has several choices of memory organization, a pixel can be represented as
a bit, a nibble, a byte, or a word. resulting in 16, 4, 2, or 1 pixels per
word respectively. Which translates to 1, 4, 8, or 16 bits per pixel. Atari's
chose to use the pixel is represented by one the bit per pixel method,
allowing 16 pixels per word in memory. This means that for the ST high res
you need 1 32k byte section of memory. ST medium res requires 2 16k byte

sections of memory, and ST low res requires 4 8k byte sections of memory. The video shifter is told what mode is being displayed and get the memory according to its pre-programmed algorithm.

Now that every one has the basic concepts of ST video memory lets look at what it takes to places a single dot on the screen. The X-Y co-ordinate is turned into an offset in memory, (X*Y)/16, next the correct bit in that word is determined, (X*Y) modulus 16, then that bit is either set or cleared to give the desired result. Now we have only taken care of a 1 bit per pixel system. If you are in ST high res your done, if not then you have to take care of the remaining bits per pixel. We already have the memory offset and the bit offset so be same bit set/clear operation must be repeated at each of the other sections of memory that comprise your display.

To summarize, to plot a pixel the offest, memory and bit, need to be calculated. Then for each bit plane the base address of that bit planes section is added to the offset and the correct bit is set/cleared.

If you chose a memory configuration where all of the bits for a given pixel are contained in the same word the number of memory access is greatly reduced. Therefore if Atari had choosen a different implementation, 8bits/16 bits per pixel with all the bits for a given pixel in the same word MOST applications would run much faster.

So why would anyone implement video memory the way Atari did? The best reason would be CAD/CAM packages, where your drawings exist in many different planes. I can only guess at Atari's reason, so I wont. This memory organization does have other benefits. Software blitting of sections of the screen will be faster, horizontal lines can be drawn 16 pixels at a time, and polygons can be filled with amazing speed.

The INIT program is much like /etc/init in Unix. Exiting init means you are shutting down the system. When the INIT program exits, that means it's time for MiNT to deinstall itself.

If you are running MiNT from your AUTO folder, then GEM hasn't been initialized yet, so you can't run a GEM program from the INIT there. If you're starting MiNT from the desktop or any time after the desktop has come up, then you can put a GEM program in for INIT.

That would be pretty unusual. Well, there *is* an interrupt vector for the
Carrier Detect signal, but that is initially disabled and I can't imagine any
program ever needing to enable it. Also, I can't understand why the interrupt
would cause a problem even if it was enabled...

In Uniterm the CONNECT message only makes Uniterm crash, and only if I used
the auto-dialer. You're saying you get a lockup even if you dial manually?
When you're in this state does Ctrl-Alt-F6 work (list active processes)?

Well, the "simple but probably wrong" answer is:

The "right arrow" is character #3 (in hex, octal, or decimal).

Try something like:
printf("\003");

(which assumes an octal argument.)

Unfortunately, \003 does something else that I don't recall offhand,
since it's one of the ASCII control codes.

I expect that what you REALLY want is some sort of XBIOS call. I'd
love to hear what the correct call is for this purpose.

Source record: 42058
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi!

I have come across an odd problem while trying to write a program.

What I need to do is use one of the "attribute" bits that are present in files
so that I can determine if my program has made use of a given file before.
This would function much like the "archive" bit, but would save quite a bit
of disk access time.

The problem is this; even though I payed Atari for the developer information,
they have not seen fit to update their GemDos manual since it was first
printed. Thus, I do not know which of the attribute bits are presently in
use and which are not.

Could someone who does please send me E-Mail, and I will summarize the
results here.

Source record: 42042

>>
>>> Is it true that the Falcon030 only has 16 bit RAM Access ?
>>
>>Ok. My answer is simply : YES !

>Excuse me, but where did you get that from? Sam Tramiel stated in the
>GEnie conference a long time ago that it has a 32-bit bus. Also,
>somebody tested Falcon with QIndex and got 471% for the CPU memory
>test, compared to a normal ST. I don't see how this could be possible
>with a 16-bit bus. So please tell me (us) where this information came
>from?

I don't know what Qindex does, but I testet the following:
A short loop (which fits completely in the processor cache) like that:
ll:
move.w d0,(a0)+
dbf d7,ll
and another like
ll:
move.l d0,(a0)+
dbf d7,ll

The result was that filling the same amount of memory with longwords is a bit
faster than filling with words, but not twice as fast as it should be on a
r e a l 32 bit machine. I'm sorry about that
I also know that Atari states that the Falcon is a real 32 bit computer.
I also asked a few people at the Duesseldorf Atari Messe and they told me the
same stuff. My opinion is that Atari tries the same way as Apple with their
'small' Macintosh.
Anyway most of the 'Users' don't recognize a difference between
a 16 or 32 bit bus.

Perhaps somebody might try the same as I did and report to this group !

But anyway even with this small bus the Falcon is a interesting computer
and I personally will buy one anyway !

>printer data) even when the printer was turned off!

This is weird as it should work. I always use Bcostat() for this and never had
any problems. You may try to use Cprnos() instead (Gemdos 17) - returns -1
if the printer is ready to receive data, 0 otherwise.

As far as I know this is not possible. The control-chars (<32 ?) and the 'high'
ascii chars (>127 ?) are just 'non-printable characters'.
If I'm mistaken (which I surely hope :), let someone please correct me.

I'm no assembler guru, but doesn't the move.l instruction take longer
time to execute than move.w? If it does then wouldn't that explain why
it isn't twice as fast? Just correct me if I'm wrong.

>I also know that Atari states that the Falcon is a real 32 bit computer.

4239. Alert Boxes in C

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-08 23:05:21 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1992Nov8.230521.19430@oz.plymouth.edu>
Source record: 42049

Hello,

I have just recently started doing GEM stuff with Sozobon C and
have created an alert box program, very simple, it just displays an
alert box and you click the button to end the program. I was hoping that
it would not exit from the desktop though. I run Neodesk and when I use
this program, Neodesk unloads, the alert box pops up on its own blank
screen, I click the button, and the Neodesk reloads. This is not what I
want, it takes time to do the above and I want to place this programs
icon on the Neodesk desktop and be able to call it up when doing other
things just to quickly see it. How do you create and alert box that will
simply display itself but no cause the desktop to go away?
And, since I'm already here. Does anyone have any idea how to
place a graphic on the newdesk desktop and manipulate it? I do not
have any books for the ST and programming what code I have produced has
been largely through trial and error and looking in ancient ST log mags
with Clayton Walnums C articles. Any help with either would be great and
I'll try to post anything that I manage to create that is neat. Please
E-mail.

Thanks,

Stephan

>only twice as fast?

One of the major reasons will be that the "real-world tests" will be using
a program that has been compiled to 68000 code rather than 68030 code. The
'030 has many more powerful instructions (in addition to all the '000 ones).
Including:

32 x 32 giving 64-bit multiplication (and similar division)
shift-widths on indices (ie. it will effectively shift and
unshift the index register for you, up to a limit)

Why do you want to find the basepage?? If you are looking for paramters, that's the wrong way to do it...

Your library's startup code should define a variable called _baseptr (or something similar) that points to it anyway.

From: trs@doc.ic.ac.uk
Message-ID: <1dlfclINNiaa@frigate.doc.ic.ac.uk>
Source record: 42044

I have recently aquired a 1040STf to use for midi stuff. I have a couple
of questions regarding the machine.

1) What does the f mean ?
2) How can I find out which version of TOS it has ?
3) Is it possible to upgrade the memory to 2 or 4 Meg ?
4) Is it possible to connect a non-atari hard disk ?
5) What type of disk controller does the atari expect to see ?
6) Is there a hard disk driver in the TOS bios ?
7) Is it possible to connect any colour RGB monitor ?

I'd appreciate any answers to the above via email.

Thanks.

>If I'm mistaken (which I surely hope :), let someone please correct me.

Use Bconout(5,chr) to print a non-printable character (5 is the raw conout device). To do this from printf write the following:

```
#include <osbind.h>

#define BUF_SZ something big

int printf(void *wibble)
{
char buffer[BUF_SZ], *ptr;
int len=sprintf(buffer, wibble);
for (ptr=buffer; *ptr; Bconout(5, *ptr++));
return len;
}
```

Obviously this could be improved, but gives you the general idea (remember \n won't work!)

Hope this helps

Most of the things you ask I cannot answer, but I can see your last
point is not quite right. If every wheel of a car runs twice as fast,
the whole car runs twice as fast, not eight times. The double clock of
the 68030 in the falcon as opposed to the ST gives a factor 2 ONLY if
the memory is twice as fast too. Now the 68030 is indeed more
efficient (check out those bit shifts in QIndex...!) and it is said to
run at 3.84 MIPS. The ST is considered approx 0.8 MIPS, so there
should be a factor of about four. Add the fast shifter (but more
complex graphics, so not too big a difference), and the DSP which can
cut short some very CPU-intensive tasks. This should give a real-life
average speed factor of about 4-5. And include disk access; if there
really is a throughput of 3M/s (!!!) and an average access time of 12
ms (!!!) we could see some humongous speed increases here. (And
virtual memory swapping to disk would be really smooth...)

Are you sure your data started on a longword boundry? If it wasn't,
that would explain why it was not twice as fast.

John, I seem to remember having the same trouble on occasion with Bcostat() and I believe I avoided that with Cprnos() which is GEMDOS(17) that checks the status of the parallel port. You might give that a try.

>Please dont spare me on the technical info., I'd love to hear it
>(I'm sure I could understand it - I study Comp. Sci.)
>

There's a lot of confusion going on here. So let me clarify some topics:

The DSP has its own 24Bit databus for local memory. On the Falcon, the DSP has
32 K-Words of 0 waitstate S-RAM. One word is 24 bit (i.e. 3 byte) giving
96KByte local memory.

The DSP does communicate with the rest of the world (including 68K bus)
through serial interfaces. The serialinterface to the 68K bus is a full
duplex ~1Mbit/s interface, as is the communication with the external
dsp port (wich howewer is multiplexed into 8 slower channels).
Just a comment to this: As long as the data rate the DSP uses to 'fetch' data
from the 'real world' (external port) is the same (or less than) the datarate
between the DSP<->CPU/memmory, there is realy no reason to complain!

The 'prosessor direct slot' (PDS) intended for hardware PC emulators and
the like, is a 68000 buss (16D/24A) with som extra controlsignals (interupt
and buss artbitration).

I do not know if the CPU<->memory databus is 16 bit or 32 bit. But given the
benchmarks that rates the falcon to >450% i would guess it is 32Bit wide!
Surely the addressbus is 24 bit!

The builtin 16bit sound subsystem does not use the DSP. It CAN use it but it
doesn't have to. Direct to disk recording and playback can (and will) be done
with only the CODEC and the SDMA involved!
HOWEWER, when requiering more than 2 simultainious channels, you will have to
add external AD/DA converters to the DSP's external port. Only then you
HAVE to use the DSP for direct to/from disk recording/playback!

>writes:

> f> 4. Is there a version of GFA BASIC that supports the math coprocessor
> f> on an ST (as a peripheral device)? Is there one that supports the math
> f> coprocessor on the TT? Will this run under the TT RAM?

>At this point, no.

I don't think that's correct. When the copy of GFA basic 3.60 TT arrived here, I did the following quick test:

```
t%=TIMER
FOR i&=1 TO 1000
l=l+SIN(RAD(i&))*COS(RAD(i&))
NEXT i&
t%=TIMER-t%
PRINT "ohne ~TT?: ";t%/200;" sec.",l
~TT?
CLR l
t%=TIMER
FOR i&=1 TO 1000
l=l+SIN(RAD(i&))*COS(RAD(i&))
NEXT i&
t%=TIMER-t%
PRINT "mit ~TT?: ";t%/200;" sec.",l
```

The loop takes .825 seconds without and .180 seconds with ~TT, showing that there definitely is a very significant difference in speed between the TT specific rountines and those that are designed to run on all 680x0 Ataris. I haven't analyzed the code and verified if the speedup is due to FPU usage, though.
For those not familiar wiht GFA: TT is a boolean function that returns TRUE if the program runs on a TT. Programs compiled and linked carry two versions of some routines, one that runs on all Ataris and one that is optimized for the TT. Originally, the pointers to those routines are set to use the all-Atari versions. If the TT function is called and a TT is detected, the TT function changes those pointers to use the TT optimized versions. At the CeBIT 1992, they demonstrated this at the GFA stand, and claimed the speedup was in large part due to FPU usage.

>Richter have recently acquired the rights to GFA basic
>(ST only) from GFA themselves, and are undertaking a complete rewrite, with
>the intention of completely legalising the package.

>They may add this support - however I have no information either way.

According to what Richter told me on the phone recently, the GFA
version developed by them will run and be supported on all
Ataris, including the Falcon, and it will run under MultiTOS.
This is also what Richter announced at the Atari Messe.
Oh yes, and the support will not be continued to be done in the
clumsy way described above, they assured me at the Messe. So save
your sneering remarks :-)

4253. What about Flash II?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 01:35:08 UTC
From: ntomczak@vega.math.ualberta.ca
Message-ID: <ntomczak.721359308@vega>
Source record: 42057
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

My friend, for some reasons not entirely clear to me, loves Flash.
Currently he is searching for a reasonable terminal program which
would run smoothly on his TT. He dials quite often to places like
Compu$erve and Genie. File transfer protocols used there are
hence a must. He was thinking about upgrading to Flash II but
he would like to here from users of this terminal program if
this is a reasonable thing to do. He tried Connect and FZDT
and so far he is not impressed. He knows about Storm but tells me
that an upgrade price makes Flash II more atractive. Besides he
is alergic to Basic.

If you have some stories indicating that Flash II is good

>
>In Uniterm the CONNECT message only makes Uniterm crash, and only if I used
>the auto-dialer. You're saying you get a lockup even if you dial manually?
>When you're in this state does Ctrl-Alt-F6 work (list active processes)?

Yes, this occurs even when I am manually dialing (and it is after
the modem sends the connect 9600 message. I doubt it has anything to do with
the CD signal because it doesn't crash while dialing - I can break out of
dialing and it works fine. No, it dies right after receiving "connect 9600"
so it proabably has something to do with some code that CoNect and Uniterm have
in common right after there is a terminal connection. Any ideas?
I cannot use any key sequence except cnt-alt-del from the locked
up state, and only if that is my only keypress after being locked up. None
of the other cnt-alt keys work. I did have it set to debug_1, and printer so
I got a: PID 7 (CONNECT)BUS ERROR: User PC = 1b7efc (base page=186cf0)
after it connected and locked up. BTW, I can still hear keyclicks, it just
doesn't do anything.

Oh, I set it up to debug when all I do is load MiNT and TOSwin, which
normally results in my inability to run any program (whether .prg or .ttp)
unless I run it through TOSwin. It dies running CoNect1.80 from the desktop
and :

pid 2 (GEM): malloc: out of memory
pid 2 (GEM): BUS ERROR: User PC=e33d88 (basepage = 489d0)
pid 5 (GEM): malloc: out of memory
pid 5 (GEM): malloc: out of memory
pid 5 (GEM): malloc: out of memory
pid 5 (GEM): malloc: out of memory

Right now I am using UNITERM, and that was after using alt-1 to
auto dial my mainframe. Did you use the mouse auto-dialer to have your
problems or does the alt-# also give you lockups? I have noticed that
trying to use the mouse menu locks up my machine, even before I get to dial
with it - the menu comes up briefly and then disappears, and it is locked from
that point on. Darn, Uniterm takes over cntl-alt1 and cntl-alt3 or I'd
set the debug before I use the mouse, but since it does, I can't debug it (I
have to set Uniterm to GEM autoboot (from desktop install app autoboot) or
I can't get it to run.

4255. My problems with MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 03:20:39 UTC
From: baffoni@aludra.usc.edu
Message-ID: <1dn9q7INNk52@aludra.usc.edu>
Source record: 42056

Hello all,

Well, using the debug_1, and printing it out, I have found something
that might be causing my problems with MiNT.

Using MiNT .95, with _just_ it running in the autofolder, from the
desktop I run CoNnect1.80 and I get one "pid 2 (GEM): malloc: out of memory"
and then the rest (about 11) are "pid 3 (CONNECT): malloc: out of memory"
except towards the end there is a "pid 3 (CONNECT): Bconmap: mapin failed".

So does anyone know why I am getting all these failed mallocs?

Can someone recommend an accelerator board which allows for the installation of a math-coprocessor. Also of interest is one which has capacity for additional memory. Do-it-yourself projects are also of interest provided I don't have to produce my own Printed Circuit Board. It is for a an 520 STfm which has already been upped to 1Meg on the motherboard. What have people used that is good and what is bad. I also do not have unlimited money to spend (who does?).

4257. Raster Copy [for window scrolling]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 06:43:50 UTC
From: mforget@elfhaven.ersys.edmonton.ab.ca
Message-ID: <H.KtV1EXXhvs6@elfhaven.ersys.edmonton.ab.ca>
Source record: 42075

Hi!

I am having a problem with a program I am writing. I need to display
a text file inside a window. Now, the actual process of setting up and
writing the information to the window is not a problem.

Scrolling the window (fast) is the problem.

The only method I know of (that I have been able to use) is to redraw the
entire window when a scroll was needed. This is, to say the very least,
extremely slow. I know that there are faster ways to do this, one of
which would seem to be a raster copy. After all, would it not be faster
to simply move the last twenty lines up two lines, and then draw the
new information at the bottom of the window?

In short (long?) I would be grateful to anyone who could share with me the
secrets of window scrolling. The faster, the better. To keep things legal,
though, I imagine only VDI calls should be used.

I have also heard that the speed of output to the window can be increased
by aligning the window on a sixteen bit boundary? How would this be done?

4258. Ethernet for the Atari ST ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 11:40:40 UTC
From: scgk@dcs.ed.ac.uk
Message-ID: <BxI0Ft.MHD@dcs.ed.ac.uk>
Source record: 42060

I have been wondering recently whether there is an Ethernet card or suchlike available for the ST.
I have been discussing networking with freinds recently and I assumed there would be come kind of ethernet interface available but I have checked all the magazines and I cannot find one.
This strikes me as odd especially as ethernet intefaces are available for everything else under the sun.
Is there is any reason why the ST should be an exception.

Simon.

From: hutch@bellman.lanl.gov
Message-ID: <1992Nov10.150809.23739@newshost.lanl.gov>
Source record: 42063

OK, I don't have a Falcon yet (I'm in good company, eh?) but I am interested in its sound capabilities, particularly for arcade game support. If one wished to incorporate some really good sound effects and/or music when writing a program that would support the Falcon's DSP, what formats would be best? Sampled sounds using something like ST Replay or the Falcon's own D2D capability or something else? Wouldn't sampled sounds require a lot of disk space? What other options should be considered?

Sorry for the naivete, but I know nada about sound & musice (obviously). :)

If you're going the TOS route to output (rather than the VDI route) then use the BIOS Bconout routines, and use device 5. Output on this device is not interpreted by the VT52 emulator and you get all the available characters. This is documented in most ST books.

>seems to be an argument going on about this).

The Falcon RAM board that was shown in the German Magazine C'T had 80nS
nibble mode DRAMS.
A conventional memory design using these and a 32 bit bus should give you a
bandwidth around 56Mb/S.

Note that if the bus is only 16 bit wide, then the memory is only 28Mb/S, and
that is impossible, because the video uses 32Mb/S in the true-colour mode and
in the 8bit VGA modes.

Atari have chosen a similar implemention of the true-colour mode, it uses
1 word/pixel.

>So why would anyone implement video memory the way Atari did? The best reason
>would be CAD/CAM packages, where your drawings exist in many different planes.
>I can only guess at Atari's reason, so I wont. This memory organization does
>have other benefits. Software blitting of sections of the screen will be faster,
>horizontal lines can be drawn 16 pixels at a time, and polygons can be filled
>with amazing speed.

The interleaved bitplanes are pretty fast for most things, for example sprite
drawing. And I guess that the most important thing - seen from Ataris point
of view have been that the screen-paint routines is the same, no matter how
many bit planes that are in use.

But I don't think that any 16 bitplane h-line or sprite routine is faster than
good 1 word/pixel implementations.
(I wonder, does the Falcon have the same Sample-and-hold logic as the TT?
Does it work in the true-colour mode?)

From: grier@bnr.ca
Message-ID: <1992Nov10.181544.15794@bnr.ca>
Source record: 42069

When I downloaded MiNT 0.95B from GEnie a couple months ago
the README file mentioned that it will load files with the
extension "XFS", from the "/mint" directory, at initailization.
From this I can assume these are supposed to be extensions to MiNT.

Basically what ".XFS" modules are available in the public domain?
Also what is the basic template for creating a ".XFS" file?

On another Note.
Someone asked what my "mint.cnf" file looks like. Well I just
use the one that came with MiNT, with no modifications. I know
sort of boring, but it works for me.

>everything else under the sun.
> Is there is any reason why the ST should be an exception.

No, absolutely not. There are at least three ethernet adapters
for the Atari ST/STe/TT computers, namely:

PamsNet: This ethernet based Atari network allows you to network
up to 127 Atari computers. There are three versions of the
adapters, one for ACSI, one for the Mega Slot and one for the VME
slot. PamsNet uses a special network protocol, but TCP/IP and a
gateway to Novell are available. An unique feature of PamsNet is
the availability of a server for a VAX under VMS, which allows
transparent access to the VMS filesystem over the network.
BioData: Another ethernet based Atari network. I don't know if
there are other adapters than those for ACSI for BioData. TCP/IP
is available, and since BioData is also available for DOS PCs,
they can be integrated without any problem.
Riebl Card plus: I mostly know about this one from the net. It
seems that the network software associated with the Riebl card is
slow and flaky, but it seems to be the only ethernet card for
Ataris for which technical documentation is publicly accessible.
A group at the TU Wien has developed a TCP/IP package for the
Riebl card.
It seems that a main difference between ethernet boards for the
Ataris and boards for PCs is that the Atari boards tend to be
available only as a package with hard- and software, and the
technical information is not available to everyone. At least
PamsNet requires you to sign a non-disclosure agreement before
they give you programming manuals and such, as far as I
understand things.

I hope you can use this info. We have PamsNet here, feel free to
mail or to post if you're interested in additional information.
Of course, I'd love to get into contact with other PamsNet users.

4270. Re: Falcon BUS..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 18:22:44 UTC
From: jornmoe@fredrik.atari.no
Message-ID: <H.TDkoZrASUmQ@fredrik.atari.no>
Source record: 42064

In <H.WTkwfzCLUbE@fredrik.atari.no>, Joern Moe writes:

I'm realy sorry about the original posting, cause it contained some realy
confusing errors. I realized it when browsing through the Motorola
documentation on the DSP56001 and a article in ST Computer.

The folowing is complete nonsense:
>The DSP does communicate with the rest of the world (including 68K bus)
>through serial interfaces. The serialinterface to the 68K bus is a full
>duplex ~1Mbit/s interface, as is the communication with the external
>dsp port (wich howewer is multiplexed into 8 slower channels).
>Just a comment to this: As long as the data rate the DSP uses to 'fetch' data
>from the 'real world' (external port) is the same (or less than) the datarate
>between the DSP<->CPU/memmory, there is realy no reason to complain!

The corect information is:
The 68K bus <-> DSP communication goes through a Byte wide (8bit) DMA (on the
68K bus that is) channel and at 1Mbyte/s speed. The external DSP conector is
a serialinterface capable of 1Mbyte/s speed. If there's no hidden restrictions
on this serialinterface (e.g. fixed multiplexing into 8 channels) one could use
this to do upto 500Khz 16Bit one channel sampling or a 8Mbps modem (gee, wish
the phonesystem could handle this:-)

The rest of the original posting was, to my knowledge, corect!

4271. Installation of TOS 1.4 (6 chip set)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-10 18:36:07 UTC
From: snoret@egon.unx.sas.com
Message-ID: <BxIJo7.F0F@unx.sas.com>
Source record: 42068

I just got my TOS 1.4 6 chip set from Toad Computers, but they didn't include any instructions! So, now I've got my ST 'naked to the world' and am afraid to just start pluggin in these chips without knowing what order to put them in. Here is the layout of the TOS sockets:

```
------------- -------------
| | | |
| | | |
------------- -------------
U4 U7
------------- -------------
| | | |
| | | |
------------- -------------
U3 U6
------------- -------------
| | | |
| | | |
------------- -------------
U2 U5
|| ||
\/ \/
to MIDI ports to Cartridge Port
```

Now, the question is... In which socket does each TOS 1.4 chip go??? The set I have has two sets of three chips. Set 1 - L0, L1, and L2. Set 2 - H0, H1, H2. Will someone please tell me the order to put them in. I got 'trigger happy' and have already pulled my old TOS 1.0 chips out, but have successfully put them back in. (i.e. it boots and works ;)

I searched through all my FAQ and saved news articles, and I even downloaded the TOS 1.4 Discussion files from GEnie, but nothing had the installation instructions. HELP!!!

Thanks alot in advance,

Rick

From: ut@informatik.uni-kiel.dbp.de
Message-ID: <1dqhg7INN5l6@samson.informatik.uni-kiel.dbp.de>
Source record: 42082

Hi eveybody!

I got a problem with MiNT Version 0.95, that I have not got with other
Versions.
I worked with only MiNT, the gem.prg started from MiNT, and then I
switch to tcsh.prg (BTW MiNT + tcsh + lots of memory is the finest
thing on an Atari ST, thanks Eric !).
I have an _old_ 520 ST+, upgraded to 4 Megs with TOS 1.02 (perhaps
this is the fault) and a harddisk driver for PC-AT bus drives.
I have no trouble using GNU-make or the make, that Sozobon-C uses, but
after a while through hardly compiling, I got errors from the GCC,
that he is out of memory. In all other Versions, I never got _this_
problem, compiling the same Program.
After Resetting, all works normal, and I can compile everything
without errors.
Am I just need TOS 1.4 or what???
Uli

I am using GFA Basic on an Atari ST (1/2 meg memory). I have been trying to use the following code to move a sprite around. The problem is the flickering on the screen. I have an idea that page flipping or the command VSYNC might help, but do not know how to use them.

Here's the code :

```
CLS
RBOX 10,10,100,100
GET 9,9,101,101,box$
FOR i=1 TO 100
CLS
PUT 10,x,box$
NEXT x
END
```

Also, is it possible to load GFA Basic programs with the .BAS file extention (I belive these are from GFA Basic 1.0). When I try to do this I get an error message saying 'Not GFA Basic version 3.5 file' :-(

Please direct E-mail to matthew@hiatech.com.au

Thanks in advance,
Matthew Smith-Stubbs

Samples do take a lot of memory/disk space but due to the DSP having various in built tables, i.e. A-Law and U-Law, it is capable of being able to compact samples by up to 4:1 and acording to the comp.compression network should be able to compress screen data by up to 26:1.

:

Forget it!

Installing it on a harddisk MIGHT be possible if you do some VERY serious hacking (involving writing your own harddiskdriver and modifying the program to use this one and simply copy complete disk images onto harddisk)

F1GP does work on a 520 (I think) and will have to run from a VERY low memory location, screwing up everything (including 99% of all harddiskdrivers) and since it doesn't use gemdos() file access you'll have to rewrite the "file" routines anyway so it involves a LOT of work even for the MOST talented hackers. My advice is: Write a letter to the publisher and tell him why you won't be buying any more of their games.. Might work! :)

Btw, an alternative is to get Vroom which isn't on that many disks :)

Cheers,

- Torbjorn

>though, I imagine only VDI calls should be used.

It seems to me that you should use the VDI(109) function, which seems to be called vro_cpyfm() in standard C libraries. I don't know though, whether this function will work properly with overlapping rasters, that is, whether you'll have to copy the raster to some buffer first and then copy it from the buffer to its destination, or you can copy blocks directly from source tor destionation.
To be prepared for new tos versions, you should restrict use of this method to the top window. I've seen that with MultiTOS, background windows still have arrows, and I imagine it's horrible if you're trying to devise an algorithm that tries to use the blocks that wades through a rectangle list, trying to reuse available fragments by block copying and filling in the gaps by drawing.

>I have also heard that the speed of output to the window can be increased
>by aligning the window on a sixteen bit boundary? How would this be done?

I never did it, but I figure you could do (in GFA):

```
PROCEDURE align_window(w_handle&,flags&)
LOCAL x&,y&,w&,h&
~WIND_GET(w_handle&,4,x&,y&,w&,h&)
x&=(x& MOD 16+1)*16
~WIND_CALC(0,flags&,x&,y&,w&,h&,x&,y&,w&,h&)
~WIND_SET(w_handle&,5,x&,y&,w&,h&)
RETURN
```

This should align the workspace of the window by a 16 bit boundary. By manipulating w& the same way as x& above, you can force the window width to be a multiple of 16, which can be convenient with windows containing text.

>
>I have also heard that the speed of output to the window can be increased
>by aligning the window on a sixteen bit boundary? How would this be done?
>
To scroll up a window, one _must_ go along the rectangle list (the window
might not be on top) and scroll up the contents of every rectangle.
If the region is high enough, use vr_cpyfm() to copy the lower part of the
region to the upper and the redraw the lower part, as the new things
could have lain under another window.
An alignment to a 16 bit boundary is used to speed things a bit up, especially
text output, as the pixel to write dont have to be shifted around so much.
To align a window,make sure that it x-coordinate of the _inner_ left edge
is divisible through 16, and the do a wind_calc() to calculate the outer
bounds of the window, then make it open there or move it there or what so ever.

Hope that helps

Currently, there's one file .XFS module available which lets you use a Minix
file system under MiNT. Look for mfs???.zoo.

Does anyone out there have MiNT 0.95 working with Codehead's MultiDesk Deluxe? I can't get it working, even with a virgin copy of MDD. Unfortunately, I don't know off the top of my head which version of MDD I'm currently running. I'll check on it in the event that it's important.

It _does_ work with MiNT 0.94, however.

Thanks for any info.

Well, if this is true, then the Falcon is doing some kind of
multiplexing.... sounds like a "68030SX" type of performance.

vro_cpyfm() works, and it deals properly with overlapping rasters, so you don't have to use a buffer--wouldn't want to, as it consumes a huge amount of time. Thank heavens I checked and ditched the buffer...

There's a package on atari.archive, that's been languishing in the atari/New directory for some unknown time called wx_lib10.zoo. It's a window'd output library for C, and it emulates printf() and puts() with scrolling and all. Pretty soon I'm thinking of giving it VT100 capability.

Oh, yeah, I never saw any need for word-alignment--I can scroll text fast enough without it that it's unreadable.

Later,

4291. C programs in GEM

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 02:42:58 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1992Nov12.024258.11229@oz.plymouth.edu>
Source record: 41994

Hello,

I sent a message about 1 week ago relating to alert boxes and programs to create them, and the fact that Neodesk and even the regular GEM desktop boots out, runs this program that displays an alert box and then reloads the desktop. What I want is to be able to put that alert box up with the desktop dropping out. It must be POSSIBLE! One person responded (and I thank them) but suggested I write an accessory instead. I'll do that if that is what it takes, but I have no books nor any way of getting any GOOD ST books that I can see. I have a Toad Computers catalog, but they do not seem to have any books listed that sound like what I'm looking for. What I really need is some guidance, how do I write an accessory? I can program in C and C++, very well in fact, but if you don't know the commands that exist it is difficult at the very least. I'd also like info on line-a commands for direct screen access (this is what the manual says Neodesk uses.) Surely someone out there knows some information and has time to help a fellow ST owner, I have some ideas for programs that I have never seen on the ST and want to implement them, which could be beneficial to all ST owners, but I need someone to help me a little with the commands first. Or at least give me the publisher or whatever to get a good GEM book, should include AES, VDI, and line-a routines.

Thanks, please E-mail

Stephan

>except towards the end there is a "pid 3 (CONNECT): Bconmap: mapin failed".
>
> So does anyone know why I am getting all these failed mallocs?

I would ignore those messages; as I recall from reading the source code (I noticed these messages a while ago myself) the reason is that when MiNT intercepts the Malloc system call, it first tries to execute the Mxalloc call which currently only exists in the TT's TOS. This call fails on any non-TT, which causes the "malloc: out of memory" message. Then MiNT calls the regular TOS Malloc routine, and that usually succeeds. Likewise for the Bconmap failure, that call also only exists on new TOS. (Of course, if you're actually running on a TT or with TOS 2.06 or 3.06, then I'd guess the failures are genuine... You didn't specify what machine you have.)

Looks ok there, although there would be a lot of situations where the
68030 will run out of cache memory and will stall waiting for the DMA
to finish. I guess that someone has to do actual performance benchmarks.

Also what we need to determine how likely will the 68030 stall is
how many cycles it takes for the DMA stuff to take place for bytes moved
to RAM.

4296. RE: Raster Copy [for window scrolling]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 09:57:40 UTC
From: cs90ijr@brunel.ac.uk
Message-ID: <BxLL07.3Jy@brunel.ac.uk>
Source record: 41999

The function you require is vro_cpyfm(), it _will_ copy overlapping blocks to/from the screen or memory buffers. Example:

```
WORD pxyarray[8];
MFDB src, dest; // Memory Form Definition Block

/* pxyarray contains the VDI rectangle
*/
pxyarray[0] = src_x1;
pxyarray[1] = src_y1;
pxyarray[2] = src_x2;
pxyarray[3] = src_y2;
pxyarray[4] = dest_x1;
pxyarray[5] = dest_y1;
pxyarray[6] = dest_x2;
pxyarray[7] = dest_y2;

/* fd_addr is the address of the 'form' buffer
* if it is NULL then the VDI fills in the other information
* in the form structure
*/
src.fd_addr = NULL;
dest.fd_addr = NULL;

/* perform the raster copy
* in this example, a block of screen is moved to some other
* (possibly overlapping) part of the screen
*/
vro_cpyfm(handle, &src, &dest, pxyarray);
```

Hope this helps.

4297. CPX v1.00 Bug?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 10:16:21 UTC
From: cs90ijr@brunel.ac.uk
Message-ID: <BxLLvF.4C1@brunel.ac.uk>
Source record: 42000

I have just started to write a simple CPX, using CPX v1.00. It appears that there is a bug in the XControl redraw code. I did the following:

. open XControl from 'Desk'
. move window to the left/right a bit
. get 'Desk' About... dialog box up
. click [ok]

Now, *sometimes* XControl misses a _single_ pixel line along the left edge of the redraw area.

i.e.

```
+---------------+
+--------| | |
|===Contr| / \ |
| | |
| | Atari.... |
| | |
+--------| |
| [ OK ] |
+---------------+

+--------|----------+
|===Contr|l Panel===|
| | |
| | |
| | |
+--------|----------+
```

^single pixel line left.

This problem seems to depend on the 'alignment' of the XControl window on the desktop. Has anyone else had this problem? What is the latest version of XControl?

4298. Co-operating processors on the Falcon

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 13:16:20 UTC
From: andrew@minster.york.ac.uk
Message-ID: <721574179.11857@minster.york.ac.uk>
Source record: 42008

If the Falcon is multitasking how will the operating system
ensure that memory access by the DSP are safe? Will programs running in the
DSP get swapped in and out or is it used like a 'dumb' peripheral which
processes have to contend for? I wonder how machines like the NeXT do it?

Will this also mean that two assemblers are needed too? One which
programs for the 68030 CPU are written/compiled and one which is used for
the 56001 DSP. Writing programs for the Falcon will be complicated. First
I'd write a program in C for the CPU and then one for the DSP(?) and somehow
link the two so that the DSP program is downloaded into the DSP where it is
initiated by the main program?

I'm sorry if this all sounds a little naive but I've never explored co-
processor systems but when I get my Falcon I'll have to.

-Andrew.

P.S.
Will it be possible to perform JPEG conversions on the Falcon using the DSP
so that they are 'super' fast? The conversion programm will obviously have
to read and write from main memory which is where my question about security
on memory access comes in for multiprocessing systems.

4299. PamsNet and VMS: Activating the TASK-object

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 13:49:59 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1992Nov12.134959.178416@rrz.uni-koeln.de>
Source record: 42002
Cross-posted to: vmsnet.admin,vmsnet.networks.misc,comp.os.vms,comp.sys.atari.st.tech

Hi VMS gurus,

a while ago we started networking our Atari computers with
PamsNet. We also purchased a server program vor VMS for having
the VAX serving its files to the Atari network. This works such
that a program is run in a batch queue under the PAMSNET account,
which was created for this purpose. This process waits for user
requests to access their directory. Upon such a request, the
pamsnet program starts a server process under the account of the
corresponding user, enabling him to access his/her VAX files over
the Atari network.
However, for this to work properly, it is necessary that "the
TASK-object of VMS is activated for local users" (from the
PamsNet manual, translated by me). Could some kind soul please
explain to me what we are supposed to do? Preferrably in the form
of a sequence of commands to type in, as our knowledge about
several corners of VMS is very limited.

Followup-To: vmsnet.networks.misc is set.

Thanx in advance,

Greetinx, Jan

4300. Scrollable list boxes

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 14:08:16 UTC
From: hrs@aber.ac.uk
Message-ID: <1992Nov12.140816.14051@aber.ac.uk>
Source record: 42001

I am writing an application were I need scrollable list boxes in dialog boxes (eg. like the file selector list). Rather than write my own I was wondering whether anybody has any code already written to do this? Failing that what is the best strategy for writing a scrollable list? I have worked out that in order to make the scrolling fast and smooth I need to do some blitting, i.e.\ blit n-1 of the entries (n=no of items in scroll window) and write out the new line either at the top or bottom of the list. And what is the best strategy to write a smooth moving slider which will sit next to the list box? I have managed to write a relatively smooth moving slider but it's not perfect.

Once I've written it I'll send the source to a.a

As far as I know (I've written an SLM804 driver lately) the CPU
in an ST was free to do anything while dma transfer was taking place.
The problem seems to be that drivers often use that freedom to make
the processor poll the dma interrupt status all the time instead of
just being interrupted when the dma transfer is complete.

```
IMHO, the Falcon's '030 has 32 Bit memory access,
(with a 24-bit adress-bus)
This would explain the three standard RAM sizes :

Width x Chipsize = Total RAM
32 x 256-Kbit = 1 MB
32 x 1-Mbit = 4 MB
32 x 4-Mbit = 16 MB (max for 24 Adress lines)

BTW : *EXPANSION SLOT* and VIDEO (SHIFTER,BLITTER)
have 16-Bit access only !

I decided to upgrade to Flash II for a small price from my old Flash (1.5?) and wasn't much impressed at first. Well, I just got my free (except postage) to ver. 2.01. Some annoying bugs are gone and it is much faster. Version 2.0 didn't show much of a speed increase considering that I went from 2400 to 9600 baud. Now, whole pages are basically flashed on the screen at 9600 and above. So, the only reason for me to use Uniterm now is that the kermit setup and download procedure is more convenient in Uniterm - not a big deal though. By the way, I'm very pleased with promptness and service in general with the company in Palatine, Ill. They are very interested with any bugs that anyone finds. These bugs appear to be corrected with each new upgrade.

CUL,
Chuck

Can someone please tell me the correct way to load up disk based fonts?
I have tried to do this but always seem to get bombs. I've used different versions
of GDOS (ie AMCGDOS among others) and many font editors (FED font editor etc)
Someone told me that the fonts must be in IBM format not Motorola, is this true?
Thanks in advance.

4307. New idea regarding X-windows for the ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-12 19:02:51 UTC
From: max@knuth.cba.csuohio.edu
Message-ID: <1992Nov12.190251.13362@news.csuohio.edu>
Source record: 42006

We have terminals. They were designed to read and write text characters that would control the host. You can edit text, run programs, transfer files, and so on.

Terminals got better. They did fancy escape sequences so that you could clear portions of the screen, use scrolling on portions of the screen, and even process special characters, some of which were "line-drawing" characters to make boxes and lines. This is like the VT52, VT100, etc.

Terminals got even better. They began to use graphics escape sequences to draw lines from any point to any other point, mix it with text, scale and rotate the text, etc, as early as the VT125, and Tektronix.

Now we are at a day when many personal computers can emulate terminals, and we have workstations networked together instead of a central computer with dumb terminals. Furthermore, we have X-windows and such where you can open up any number of windows on a workstation where each window represents a terminal, a game board, a picture, a notebook, a drawing tablet, or basically anything you want.

Because X-windows is free from M.I.T., and because it is so successful, and because it is so flexible, and popular, I suggest that we implement X-windows for the ST (and other computers as well).

X-windows function calls are standard, and there would be compatibility between any system (you could paint a picture with the same commands on an ST as well as a PC as well as a DECstations 3100). Because it can be implemented via modem (I know, modems are quite slow when it comes to drawing graphics remotely), you could call up a host, and it would run it's chess program on your screen: you enter the keystrokes or mouse clicks, and it draws on your screen the results.

If you could define a chess "font", where the letter "A" is really a pawn, where the letter "B" is really a knight, etc., then the host running your chess game need only send 64 characters to completely describe the board. In this case, fantastic graphics via modem is achievable.

As it happens I am running this on a TT with TOS 3.06. Sorry, I have
been posting about it quite a bit, I keep forgetting how hard it is to mentally
link posts together.

With just MiNT loaded, (no control panels, or anything) I should be
able to run, from the desktop, one .prg, right? I can't unless I autoboot a
.prg first (using the autoboot option in Install Applications - I have not been
able to successfully INIT=TCSH.ttp at all)...well, I haven't tried the autoboot
thing with anything but Connect but I don't see that that should make much
difference...I'll try another .prg just in case. However, once I have quit the
autobooted program, I notice that I get malloc:outofmemory every time I open a
window, like looking at c: or d:, but it works ok anyway (I can read the
directory, etc.). In fact, I get malloc errors whenever I open a window within
CoNnect. :(

I'm at a loss.

BTW, I haven't heard a word from Eric Smith. I guess he's still
settling in at Sunnyvale. :) Well, hopefully I can get some help from him
soon if someone here on the net doesn't fix my problems first.

4312. Help with downloading files from umich

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-13 08:17:16 UTC
From: cmmiller@iastate.edu
Message-ID: <BxnB0u.4Kt@news.iastate.edu>
Source record: 42014

I noticed (while FTP'ing) to mac.archive.umich.edu that they have a large selection of games for Atari. Most of these games had endings with ".lzh", ".zoo" or ".tos". Does one need some sort of compression programs for these files? If so what and where can I get it?

Also, as I understand it, Atari has their own system. If I download these files, and the person in Germany has the correct decompression programs, is it possible at all for her to read the disk on which I send it?

I can download directly onto Mac or DOS formatted floppies.
I presume I download the files as binary data.

Is there really anything I can do without having access to an Atari?

Any help would be greatly appreciated. Please respond via e-mail since I don't read this newsgroup regularly.

Thanks a lot in advance!

Chad "cmmiller@iastate.edu"

^^^^^^^^^^^^^^^^^^^
of course, when running a single tasking AES, this is not a problem. I think
with MultiTOS lots of programs of the highest standards will have problems
with scrolling.

Rounding on an 8 bit boundary BTW is sufficient. Apart from the wind_calc you
should have a small edge of white space before you start v_gtexting. It's very
ugly if you stick the letters to the left edge of the window.

Kommentar zu A14548@HB in der Gruppe CS.ST.TECH
C>The truth is: the F 030 has a internal RAM port with 16 data and 24 address
C>pins. (i've seen the specs and I've seen the layout)

(looking at the developer specs... Ah! Found.)
Right, this is an expansion slot, carrying data bits 16-31 only. This is not
the CPU bus!
This expansion slot is meant to be 68000 compatible, therefore the limitation.

C>On the other hand a german magazine has tested, that the processor accesses
C>the RAM as if it was a 32 bit memory.

This is right.

Please post this answer to the public in CS.ST.TECH, as I have no access.

The 68030 can't _access the bus_ while DMA is taking place, but it can
continue to do anything else until it requires bus access.

There's also a problem with caches and DMA. Because a cache may contain
data that has yet to be written to memory, it must be flushed before DMA can
take place. This prevents the DMA operation picking up any "old" data held
in main memory. Hence the processor caches are usually flushed before any
DMA operation.

I understood that the DSP was accessible via OS calls. That way it is
simple to load a code to the DSP, or to execute it. And it's much
cleaner. I think it would be comparable to the way the keyboard
processer in STs can be used (had anybody actually tried to? (not that
those 128 bytes(?) allow for serious things, but just for fun)).

I've heard there will be an OS call to do this, using the DSP. This is
of course VERY stalwart.

No, programs running on the DSP run in their own private memory. The DSP
has its own bus and 32 KWords of memory, in which it can run many processes
concurrently (well, give them shared time anyway). The DSP cannot do memory
accesses to main main memory, so there is no conflict with the memory
management of the 68030.

>
>Will this also mean that two assemblers are needed too? One which

Yes, there are separate assemblers/compilers for writing DSP code and normal
68030 code. I believe the developers have been sent the DSP compilers and
docs quite a while ago. Your linking idea is on the right track, but I
imagine it to be more like using assembly code in your C programs : you
write your normal interface and all in C, for example, then write the
super-duper high-speed compression algorithm in DSP code, then your normal
code sets up the DSP with the appropriate data and sets it loose. Kind
of like you call the SDMA sound engine to play a sound (hands off as far
as your program is concerned), you'll call the DSP with a bunch of parameters
and let it go to work.

They have mentioned this, and it probably will be able to do these in real
time. Like I said, the DSP can't access main memory, I think it has to

request a DMA transfer or something to get to memory. A previous poster said that the DSP-68030 bus interface was capable of 1 MB/sec or so, but this spec could be off. At any rate, it will be fast enough to allow the things you were mentioning. (JPEG, virtual FAX, etc)

>with 4 channels.

No. The Falcon has 8 internal channels that mix to two channels on the output (1/8" mini jacks), but it handles the 8 channels independently internally. If you wish to input more than the 2 channel input, you need to use an external AD(and probably DA for separate output) and connect it to the DSP connector (which can then interpret/redirect/process the information). Oh, and they decided to be backward compatible so you have 8bit sound available for those soundtracker modules (Lord knows I have enough to worry about that too :).

>processor, or does the processor have to halt while the blitter is
>working?
>

Why does everyone keep asking if the CPU has to halt whenever some sort of coprocessor is operating (DMA, VIDEL, BLiTTER, whatever)? The whole point of even having a coprocessor is to let the CPU churn away at other stuff while the coprocessors grab the data and deal with it, all by themselves. What would be the point of having a blitter if the CPU had to halt and wait for it to finish? You might as well have the CPU perform the blitting operations then (and yes, before someone complains, the blitter does do more stuff than the CPU could alone, and probably more efficiently too).

In conclusion, the CPU does not HALT for anything -- you may run into some bus contention when DMA or similar operations are taking place, but that won't generally affect the CPU much. The whole idea of all the COprocessors is that they can run in tandem with the CPU and take the burden away from the CPU on tasks such as transferring, say, 10 MB from the hard drive. Such tasks are trivial to implement so it's stupid to waste precious CPU time doing them.

Sorry if this seems a bit out of hand, but think about it : why do coprocessors exist on the Falcon and what do they accomplish? It's really a simple matter. :-)

4323. Ajax + TT problems

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-14 10:56:46 UTC
From: michael.smith@f842.n800.z3.fido.zeta.org.au
Message-ID: <X0c00426@Kralizec.fido.zeta.org.au>
Source record: 41741

Okay, having finally found a 1.44M Epson drive, and swapped the fascia from my old 720 onto it, and blown $35 (ooer) on an Ajax chip, I find myself depressingly faced with the following problem :

It doesn't work.

More specifically, the Ajax controller seems to be the guilty party - I can format 1.44's with the 1772 (scarily enough) so I know the clock generator etc. is working fine.

However, with the Ajax installed, I cannot read or write either 720 or 1.44 disks - at startup, the drive emits a rather novel 'beeping' noise, rather like a very fast seek, and the non-FDC things (side select etc) seem to work fine.

Is there anyone here with hardware experience on the TT that can give me some idea of where to start looking?? - I've already returned the Ajax once for a new one (the store was very kind about that) and I don't want to have to go thru their entire stock of them looking for one that works - accusing someone of having faulty stock doesn't make you many friends.

Well, Blox and HacMan II, which you can FTP from atari.archive, both
work on all Atari machines (including the Falcon). Blox supports DMA
sound, but only if your register. These games even let you return to
your work after playing without leaving your desktop totally trashed.
(What a concept!)

Both of these games are by the editors of ST Format. Oh, WAIT A
SECOND, they're actually by me. Sorry. Shouldn't let myself get
so absorbed in these Atari magazines. :-|

ST's, STe's and TT's have an old design... doesn't mean is better. :-)

|> larger number of coprocessors -- it's working on the same tried and true
|> concept which has worked on almost all SISD microcomputers for ages...

True, having coprocessors always helps (or in the average case, it always helps). But between a computer that has a separate bus for the coprocessors and another for the CPU, so there's none CPU bus contention, that computer will run much faster under some situations.

Since I don't want to start a flame war either (:-)), I know of another computer that doesn't run into this problem by providing two kind of buses (some people can imagine what computer I am talking about). On that computer, if the CPU is forced to access the coprocessor's memory, while there is heavy info traffic, the CPU slows down (on some cases

a lot). But because that computer has another bus for the CPU, when the CPU runs in its own memory, it runs at full speed (or as fast as that memory allows).

Remember the ATARI 8-bits? The machine is rated @ 1.79 Mhz and actually runs like @ 1.13Mhz. This is due to ANTIC's DMA bus contention. This is the problem I see in the Falcon. How many of you (ex ATARI 8-bitters) remember:

Poke 559,0?

This turns off Antic DMA so the machine speeds up like 30%.

Now, should the Falcon had a separate memory that only the CPU could access, this would mean that the CPU will slow down only when accessing video memory under heavy graphic modes. Same happen with other coprocessors.

Yes, this would be nice, I agree. Isn't that how the TT RAM usually works? I mean TT RAM can only be accessed by the CPU or something like that, right? Maybe someone with a TT could fill us in on how this works exactly. With the PDS slot in the Falcon (even if it is only 16/24 like has been said), perhaps you could make a RAM upgrade which would work similar to the TT RAM so that you could run programs a lot faster. I really have no clue as to how the PDS could be used, but I've heard that emulators, memory upgrades, or graphics upgrades are all possible. So maybe with a Falcon-RAM upgrade we could _really_ get the thing screaming along... :)

For h-lines, yes, but for sprites, I have my doubts - so much can be done by exploiting the separation of the bit-planes - as you can see by what the Demo programmers do. When you have 8 bitplanes, it actually becomes useful in general (and 16-bitplanes would be even better). But yes, 1 word/pixel is the Right Choice for the True Colour mode.

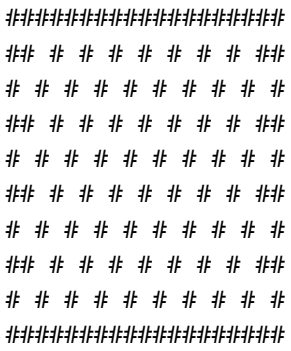
>This problem seems to depend on the 'alignment' of the XControl window
>on the desktop. Has anyone else had this problem? What is the latest
>version of XControl?

This happens with almost every acc in existence. The problem is that the fill patterns are not aligned to the object being drawn. For example, using the 50% fill pattern will give you either:

```
####################
# # # # # # # # # #
## # # # # # # # ##
# # # # # # # # # #
## # # # # # # # ##
# # # # # # # # # #
## # # # # # # # ##
# # # # # # # # # #
## # # # # # # # ##
####################
```

or



depending on where you draw the screen. The trouble then occurs when the GEM window move code ***raster copies*** your window, rather than redrawing it. If it redrew the object, all work work (although MUCH slower).

The only solution I know is to align you windows according to what pattern appears in them (eg. allign on odd (or even) pixels for the 2x2 fills, and 4-pixel boundaries for the 4x4 fills... and so on).

... or don't use the VDI fill routines.

IMO, it isn't a problem. It just looks a bit ugly on those RARE occasions when it occurs.

4332. Need HELP!!! with Memory expansion

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-16 04:05:13 UTC
From: an938@cleveland.Freenet.Edu
Message-ID: <1e76lpINN53n@usenet.INS.CWRU.Edu>
Source record: 42033

I am having trouble with adding memory to my 520 STfm.
Everything is connected according to the instructions (From the
Umich Atari archives) but the upper bank of memory will not respond.
I remember that someone mentioned a few additional modifications
needed to be put in. I noticed that the CAS1 High and CAS1 Low
lines require resistors along with the RAS line. But, what values
must be used? Besides that, I can't think of anything else but a
faulty MMU. I believe that a person named Annius Groelink? knew
what to do, but I do not have full Internet access so I can't
find the E-mail address.
One other question is: can I use Mac SIMMs for the ST
mod since they have an 8 bit data bus, (and are considerably
cheaper!!).
Thanks in Advnc,
George II Lenzer

4333. READ problem with Wangtek 5150ES tape drive

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-16 08:29:14 UTC
From: rh0083b@medtronic.COM
Message-ID: <1992Nov16.082914.18069@medtron.medtronic.com>
Source record: 42037

I have a problem with my Wangtek 5150ES and my Atari ST (host adapter is ICD Advantage-Plus ST). On the same SCSI bus is a 105 MB Quantum drive that works just fine.

Using the TAPETEST program that comes with TAPEBIOS it appears that I can write to the tape (I verified that on a SUN Sparc), but I cannot read! When I do a read, the tape moves (so the command apparently makes it to the drive), but the TAPEBIOS software hangs waiting for a status byte. After a couple of minutes the software times out, but the SCSI bus is still busy (I can no longer access the disk drive). The data buffer in ST memory has not been written to (still filled with zeroes).

Do you have an idea what is wrong here? Is my software broken? Did I misconfigure the drive?

Best regards,
-Roger

In article <1992Nov10.181900.190226@rrz.uni-koeln.de>
kim@vax.mpiz-koeln.mpg.dbp.de describes various Ethernet solutions for the ST;

In addition to that, I was aware of a genuine Atari product on that. I remember that thing was shown at the CeBit fair 2 or 3 years ago. The guy told me Atari had thousands of them in stock and they were going to ship them REALLY SOON NOW.

Since then I've never heard about it any more.

So anybody knows what has happened ?

The card shown to me was designed to fit into the bus adaptor of an ordinary Mega ST, connecting to the outside through the "slot" at the rear side of the case.

In contrast to PAMSnet and Biodata, which come in a separate case, this seems to be the better solution.

In any case, Ethernet solutions for Atari are far more expensive than for the PC (to my knowledge PAMSnet and Biodata are still around $500 or more, whereas a PC ethernet card can be obtained at $170).

This is one major reason why ST's have been obsoleted in our department and replaced step by step by PC's (sigh :-(

It does? Are you sure?? I guess you are. Anyway, I wouldn't know
anything about TT RAM-access. I'm going to get a heart attack if
Falcon turns up with a 16-bit data bus. After that I'll go hunting for
a Tramiel scalp :). Please God, don't let Falcon have a 16-bit bus!
Do you think the faster TT-RAM could be the reason why the TT would
still be faster?

4341. Using an IBM keyboard with an Atari ST

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-16 18:27:04 UTC
From: an938@cleveland.Freenet.Edu
Message-ID: <1e8p5oINNaf7@usenet.INS.CWRU.Edu>
Source record: 42039

My last posting got a little messed up, so I will try
this again. Does anyone know of a way to connect an IBM style
keyboard to an Atari ST via a D.I.Y. circuit that does not use
the MIDI ports, or the serial port? I have a newer ST which
has the mouse/joy ports built onto the back of the keyboard, so
these would have to be transplanted too. Is there any info on
intelligent keyboard interface itself? Maybe a way to transfer
that to an IBM?
My main angle here is to put my 520 STfm into a tower
case so as to save desk space and add modularity to my system.
I know that others have done this, so... If you're out there,
please give me any suggestions that you may have.

Thanks,
George II Lenzer

While I wouldn't claim that the A1200 runs every available piece of
software (particularly games), it surely runs almost any Amiga application.
Include here all paint packages, desktop publishing, illustration programs,
multimedia programs, etc. Yes, it's got a significant advantage over
the FALCON. And BTW, I know of more than 30 games that run on the A600.

|> 7) Major entertainment software producers have pledged support for the

|> the new LOW-END machine(s) [first the 600 the the 1200]

Psygnosis and Ocean have pledged support for the AGA. There is another
company that also pledged support for the AGA. AT LEAST Psygnosis and
OCEAN are MAJOR entertainment software companies.... Psygnosis ALONE
is an EXCELLENT MAJOR GAME COMPANY... a company that have dropped ST
support in some of their games...

So, I don't know about what the Falcon can claim, but at least on the
Amiga part of the statement, yes, major entertainment software producers
have pledged support.

>have understood correctly, at least my STe plays soundtracker modules
>with 4 channels.

Slight misunderstanding here.

The Falcon only has two PHYSICAL channels - ie. normal stereo, just like the STe.

As far as "voices" go (ie. internal channels), I don't see why there would be
any limitation. Since the DSP can handle 1Mbyte/s of incoming data, you
can have as many channels as you want - the more channels, the lower the
frequency. For example, just using the "1Mbyte/s" value, you should be able
to process 20 16-bit channels, each at 25kHz (20 * 2bytes * 0.025M/s = 1Mbyte/s).
Or, about 8 16-bit channels, each at 62.5kHz, which is around the published
limit.

I guess you could have 90 little 8-bit Apple Mac (11kHz) voices too, if you
wanted to.

How many instruments in an Orchestra? :-)

Also, with the DSP running at 32MHz, it has time for quite a few
instructions for fiddling with those values too, besides adding the
sounds together. Of course, when processing 90 voices at once, you'd
be pushing it pretty hard :-)

NOTE: This is all quite theoretical, based solely on the FACT that the DSP
can access main memory at 1Mbyte/s, which it can (the hard-drive controller
accesses it at something like 3Mbyte/s, so it's not a major feat). The
actual implementation would probably operate by transfering sound data in
chunks from each of the currently playing sounds, storing them in the DSP's
memory as a buffer, since reading 20 words from different parts of memory
isn't very efficient :-).

I tried PAULA & PETRA & TOS 2.06 on my MEGA ST, too! I had no problems
using this excellent MOD-Player! It is now possible to use your disk and
hear your favourite Sound!

Did you use the new PAULA 2.0d?

2.0 is actually rather new, more likely you have something on the order of 1.0.
Anyway, I understand TOS 2.05 or better is needed to format high-density, but
you should be able to use a high-density drive to format 720k.

From: elendir@inf.enst.fr
Message-ID: <2681@ulysse.enst.fr>
Source record: 41973

Warwick Allison writes
] Also, with the DSP running at 32MHz, it has time for quite a few
] instructions for fiddling with those values too, besides adding the
] sounds together. Of course, when processing 90 voices at once, you'd
] be pushing it pretty hard :-)

A 32 MHz DSP has a 16 MHz instruction clock rate. A 1 Mbyte/sec throughput corresponds to 300 KDSPwords/sec, or one interrupt every 3 us. You have time to execute 48 instructions then between each interrupt. Enough to do some pretty effects : Surround, Echo, Reverb, Basic IIR filters and much more.

If you want a demo of the sound capabilities of the DSP, watch out for the Audio Fun Machine demo at the Comdex (Personnal pub).

Enjoy.

Vincent.

4354. fontgdos and Timeworks DTP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-17 11:00:04 UTC
From: beaumont@sics.se
Message-ID: <1992Nov17.110004.9875@sics.se>
Source record: 41954

Can someone help me with a problem I have using fontgdos.

I have a copy of Timeworks DTP (the complete version 1 given on the cover disk of AtariST review). I have tried to make it work with fontgdos, and my BJ10ex printer. My problem is that immediately after I finish printing a document, drive A is accessed and then the machine freezes displaying 4 bombs. The printed document is perfect but I can't continue afterwards unless I reboot first. Can anyone suggest what is wrong and how I might fix it. If I use gdos and the gdos epson printer.sys then the thing works ok but the printed documents are only at 180dpi and I'd like both better quality and to make use of fontgdos.

To use printer fonts that are 360dpi, I have setup Timeworks using the 360dpi fonts for NEC printers and used the BJ10e printer.sys from the fontgdos package. My fontgdos bitmap cache is 400K. My system has no HD, only 2 double sided floppy drives. The startup files are in drive A and the fonts/documents are on drive B (I have a 2.5Mb Atari 520 STFM with TOS 1.2).

I'd prefer email responses as I don't always get time to read this newsgroup. My address is beaumont@cs.bris.ac.uk

p> Keith.

What language are you programming in? BASIC? (Guess not, since I can't imagine a BASIC program which needs to know its memory location) If yes, which version? I know there is a variable BASEPAGE in GfA, which points to the basepage of the currently running program (only useful for compiled programs of course, otherwise it would point to the interpreter.)

The D.E.K.A. keyboard adapter kit has received some pretty good reviews of late (most recently in Current Notes, Nov 92, pg 75). Adopting a MSTE keyboard would be the easiest, but if you must go with a PC unit, the D.E.K.A. thingie offers a good solution, it seems.

I would also like to know the answer to this query!

Now, don't send me info on how to double the rate of some clock and
pretend that a 720k drive is a 1.44M drive. I am willing to buy a
correct 1.44M drive mechanism (which makes are suitable?) and a new
set of ROM's (does anybody know Atari's parts numbers?), but I want
to get a technically correct solution.

I want to install a 1.44M drive into a Mega4, currently at TOS 1.02.

Is this possible?

Cheers.

Pete, as a minimum, you would need the new 1.44 drive mechanism, TOS 2.06, a TOS adapter kit (like the CodeHeads TEC or similar), an AJAX chip (disk controller) and other stuff I'm sure. Also, unless you get the specific Epson model drive mech, you'll have to do some surgery on your 520 case to allow for the disk eject button to fit. I'm not a hardware guru so others here could give you more specific details.

I can give you advice, however... don't do it. If you have your heart set on a hi-density drive, then just buy a MegaSTe or wait for the Falcon.

BTW, you most likely have TOS 1.0 in your early 520ST.

First of all, How does a bus work?

second, 16 bits on a memory 'bus' would seem (to me) that it could
only adress 64k. but it can adress 16megs.. or 24bits.
would the chip send 2 bytes out in two cycles to complete an adress?
thats screwy.

You can add TT ram to the falcon (32 bit ram) (or so says AtariUser)

third: Atari docs state full 32bits, it would be crime to lie about something
like that.
(of course, big corps can get away with that stuff.)

could it be that the PDS slot could be confused with another bus?
the pds is 16/24 68000 compatible. (according to my mags)
its definately not 32bits
and, its something dave small would be 'into' since he's mr. mac emulation
(the primary purpose of the PDS slot)

could a 16bit adress bus be 4-5x faster than an ST?

what was the ST bus like?
was it 16? 24?

why would atari have a dsp/videl and other 'cool' stuff in the falcon, but
then intentionally screw the cpu?

i would figure its not any cheaper to have 16bit busses...

just my observations.

Ok, sorry about this guys, but here's the final facts:

Date: 17 Nov 92 07:02:23 EST
From: Wilfred Kilwinger <72347.2124@CompuServe.COM>
Subject: Want to get something cleared up....
To: >INTERNET:jornmoe@fredrik.atari.no

>There's a lot of confusion going on at comp.sys.atari.st.tech about the
>Falcon bus: Does it have 16 or 32 bit databus (CPU <-> memory)?

This is what John Townsend (Atari Corp) said on GEnie:

Atari-ST RoundTable
Category 14, Topic 20
Message 73 Mon Nov 16, 1992
TOWNS [John@Atari] at 15:01 EDT

Once and for all..

The Falcon030 has a 24bit Address Bus and a 16bit Data Bus. The
expansion port on the machine represents that bus.

The Falcon030 can have a minimum of 1 meg of RAM and a maximum of
14 megs of RAM. Possible RAM configurations are 1meg, 4meg, or 16
megs of RAM.

-- John Townsend, Atari Corp.

Note that the Apple LC and the Classic II use the same trick and some
chips do have full 32bit access like the video logic.

****

Now, that should settle the discussion on wheter it has 16 or 32 bit bus, but
it will certainly not settle the frustration among some of you Atarians now:-/
But remember: with its low price, the Falcon 030 is quite uniq anyway!!

And while we are at it with facts from reliable sources:

>There just appeared a roumor about the reason for the delay of Falcon. The
>roumor states that an Atari official (in europe som place) said that the
>reason for delay was that new video-modes were added (redesigning of video-
>hardware) to see to that the Falcon had better spesifications than Amiga
>1200!
>Do you have anny coments on this roumor (that I may quote to internet)?

Yes, 100% nonsens.

Regards,

Wilfred

|> 600 or 1200, do you?

Talking for the A600, I believe that a lot of games will run... talking
about the A1200, still it will run a lot of games but less than the A600
due to the 68EC020.

|> | Psygnosis and Ocean have pledged support for the AGA. There is another
|> | company that also pledged support for the AGA. AT LEAST Psygnosis and

|> A500. They can't even support *current* machines, so what makes you think
|> that they can support new ones?

For the A600, they will work since they bypass the OS completely, and
the OS is the only stumbling block between compatability between an A500
and an A600. For the A1200, some of them wouldn't work 'cause not taking
into account timing considerations. But, latest Psygnosis games run fine
(on the A3000 at least) - Leander, Lemmings, Awesome...

Nope, that would be the "address bus", not the "data bus"

|> would the chip send 2 bytes out in two cycles to complete an adress?
|> thats screwy.

Somethings among those lines...

|>
|> You can add TT ram to the falcon (32 bit ram) (or so says AtariUser)

I understand that the TT also has a 16-bit data bus... someone stated
that a while ago... I am not sure about that, but since the Falcon in
some benchmarks (posted here somewhere) was about 50% as fast as the TT,
sounds logical to me...

|> third: Atari docs state full 32bits, it would be crime to lie about something
|> like that.
|> (of course, big corps can get away with that stuff.)

Yep. I remember when Apple said that their Mac used a 32-bit CPU
(68000).

|>
|> could it be that the PDS slot could be confused with another bus?
|> the pds is 16/24 68000 compatible. (according to my mags)

Could be...

|> could a 16bit adress bus be 4-5x faster than an ST?

Could be...

|> what was the ST bus like?
|> was it 16? 24?

The data bus I guess would be 16-bits. 68000 data bus is 16-bits.

|> why would atari have a dsp/videl and other 'cool' stuff in the falcon, but
|> then intentionally screw the cpu?
|> i would figure its not any cheaper to have 16bit busses...

|>
|> just my observations.
|>
Well, it actually reduces cost and makes the machine easier to implement.
Still, the 68030 has some benefits (MMU, internal cache), although I agree
that looks a little crippled in the Falcon (like on the Mac LC-II).

Some notes:

Adress bus: where adresses are specified to access memory locations.
This means how much memory can you access without bank switching.
For example, a 6502 has a 16 bit address bus meaning it can access
64k. A 68000 has 24-bits so it can access 16 megs.

Data bus: where instructions/data are read/written from/to memory
locations.

Thanks for the final facts. This means that it has the same address
bus as the A1200 (the 68EC020 has a 24-bit address bus which is 16Megs),

and the A1200 should be around twice as fast due to a true 32-bit data bus.

Oh well, still a DSP surely helps!

A DSP is a DSP is a DSP.... :-)

Message-ID: <rob.722079015@marsh>
Source record: 41972

Hi all, I am able to get hold of a home brew sound digitiser for my ST, but I will need to write the software myself. No real problem except I cannot work out how to use interupts/timers on the ST, my doc's are old and confusing and my 68000 is VERY rusty. Could someone possibly post a quick example of how I could grab data from the parallel port x times a second. I'm assuming that assembly and interupts would be required. Thanks for any help.

From: mpnolan@unix1.tcd.ie
Message-ID: <mpnolan.722090818@unix1.tcd.ie>
Source record: 41974

Ok. That's it!!!
If you are telling me that Atari put a GREAT processor,
the 68030, and then put it onto a 16 bit data bus..well!

look..

1. Atari 8-bit [atari 800]
2. Atari 16-bit [st]
3. Atari 32(16) bit (?) [falcon]

If they're next computer is 16 bit it doesn't make sense!!!

Why not use a souped up 16Mhz 68000 instead of an expensive 68030
and still only have 16 bit data bus

RUBBISH!!!

Atari aren't THAT stupid!!!! The FALCON has a 32 bit bus, till
I see it with my own eyes..

ps: has anybody seen the 16-bit bus with THEIR eyes?
(no crap please)

4371. VIDEO questions

I have been using Ataris for years to do MIDI things, but
recently have decided to get into using video projection
in my concerts.
I need to know a few things:
1. is unmodulated video available from the Mega? (this is what
I need to give to the projector)
2. what is required to do external genlock. The Mega is capable
of this...but I have not seen any boxes that hook up to
do it.
Thanks to anyone who can answer these for me.
Alan

WHAT? If the shifter has full 32-bit access to memory how much more glue could it take to allow the processor 32-bit access? I mean the memory is already 32-bit wide for the shifter after that it would seem trivial to get the processor to have 32-bit access. If this is true I may be holding on to my savings for another year or so. :-(Oh well, by then I should have enough saved up for whatever is available.

See ya then.

Apple did it first so it's ok?
Up until now the Falcon sounded pretty much perfect.
Fast '030, DSP, SCSI etc.

All implemented over a 16 bit bus.
Wonderful.

There's no place like home.
There's no place like home.
There's no place like home.

Nope - that postings still there :-(

Somehow the Falcon doesn't seem to be quite so nice anymore.

>Now, that should settle the discussion on wheter it has 16 or 32 bit bus, but
>it will certainly not settle the frustration among some of you Atarians now:-/
>But remember: with its low price, the Falcon 030 is quite uniq anyway!!

Unique, perhaps. Crippled definately.

I have owned an A500 (yes, I suppose that does make me one of the enemy)
for the past 3 years now and am saving up to upgrade to an as yes
undecided 'something better'. The Falcon looked *so* good to start
with, but *if* this is really true (I stress the if because I wait for
further postings - I still have difficulty believing it) I doubt I will
ever buy a Falcon.

Someone out there please refute this.

Just to be anal retentive (sorry, too much computer architecture and performance analysis this semester...)

The A1200 could be *up to* twice as fast due to a true 32-bit data bus assuming that the bus was a bottleneck in the system (likely for some applications, unlikely for others). This also assumes that everything else between the two systems are identical, which, of course, they are not. About the only conclusion that anyone can draw with any certainty is that the A1200 might be faster in certain applications, while the Falcon might be faster in others. (This is about as precise as "Well, it might get colder when winter comes around then it might warm up again when we get to spring" :-)) There is also no way to "know" for sure until both machines are out.

In any case, who really cares which one is "faster" (meaningless term without a context) or "better" (another meaningless term when without a context)? Most of the Atari fanatics on the net I have been in contact with wouldn't think of buying an Amiga and most of the Amiga fanatics on the net I have been in contact with wouldn't think of buying an Atari. (This is not to say there are no reasonable Atari owners or reasonable Amiga owners. Of course, there are. However, you can only do so much analysis when you are missing most of the facts.)

Frankly, I hope both computer companies do excellently and maybe someday we won't have such a PC clone dominated industry. (I just say this because I don't like working on the PC platform.) I know, dream on...

C'mon folks, let's get real here, OK?

Personally, I don't give a twit if the Falcon has a 32, 16, 8 or 2-3/4 data bus... as long as it performs and performs well in consideration of its cost!

That's like saying, I don't like this program because it was written in BASIC (or pick your favorite "non-favorite" language). Even though it may be the greatest thing since sliced bread you still don't like it? Who cares?

Sure, a lower throughput bus probably would limit the _potential_ of the machine, but there _are_ considerations that were made for compatability with older ST/STe software. You don't have to like it, but be reasonable.

All IMHO, of course. :)

4380. Spectre GCR troubles

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-18 20:01:17 UTC
From: dtarico@violet.ccit.arizona.edu
Message-ID: <1992Nov18.130117.1@violet.ccit.arizona.edu>
Source record: 41982

My spectre GCR has been acting up recently. It is pretty stable running from the hard drive, but the floppy drives have been having trouble. I am running a Mega 4 ST, Spectre 3.0, and system 6.0.5. I also have an external floppy drive. The internal drive always gives errors on the 8 sec/track part of the GCR test. That could be related to interference, and since I have the external drive, I just use it. The external drive passes all of the GCR tests. But under Mac mode, I get some weird problems. Disk errors happen fairly often. What is even stranger, is that I can copy files to and from the hard drive and things work ok. But when I try to use files on the floppy drive, I get errors. For example, I work with Macwrite a lot. If I copy the file from the floppy to the hard disk and work with it there, I have no problems. But if I try to work with the file on the floppy disk, the file gets screwed up pretty bad. Real Macs don't have any trouble working from the same disks that the GCR has trouble with.
Does anybody have any ideas what could be causing this? Yes, I have checked all the cables, tried adjusting the dashpot. Is Macwrite not completely stable under Spectre? Could it be that something is messed up on my hard disk?
Thanks for any help!

>
> All IMHO, of course. :)
>
> _____________________________ John "HUTCH" Hutchinson ____________________________

I agree, I am not thrilled by this but I'll just keep the TT another
year or so. (My wife is wiping the sweat from her brow)

And on another thought ...

The Atari lineup will look as follows:

Processor Cost 85mb HD Color Monitor
1040STe $399.00 $500.00 $350.00
Falcon030 $800.00 $300.00 $400.00 (low end multi-sync)
TT $1200.00 $300.00 $400.00 (see above)

Some people will agrue that monitors are not needed for the 1040 and
the Falcon, because they already have a monitor. But to a new computer
user they will need a slow monitor for the 1040, or a multi-sync for
the Falcon. TV's are good for viewing animations but don't try and
use them as a monitor.

As strange as it may seem to most Atari Fanatics these are reasonable
prices for the each machines target market. What we need is visibility
in the market place. PC-Clones were not sold by IBM advertising them.
They were sold by being compatible with, and even better than, the IBM
PC.

Macintoshes are not sold on advertising, they are sold on the basis
of what they can accomplish for the user. The advertising just reminds
you that they are still available. Something Atari should think about.

Yet another thought. <- YAT (Could this be the next Unix command?

Just enjoy your machine. My systems do everything I want, at a price I
can afford. (My wife has other opinions on this)

I just got home from Comdex. Yeah, the AFM is a nice little toy. (All kinds
of sound effects in realtime.)

As for sound channels, I think Warwick has it right on the money. (Although
trying to implement an actual orchestra, and then only going to 11khz sampling
is going to put a real damper on your instruments, eh? }-) My company is
currently showing a single-line voice-mail system on the Falcon (most of the
group is still in Vegas right now) but it would be trivial to bump it up to
6 or 12 phone-lines per sound-track, giving a maximum capacity of handling 96
phone lines simultaneously. (I suppose we would have to be nice and leave
at least two channels free for system audio, though, unless the machine was
used as a dedicated automated response system...)

Well, there was no Falcon040 on display at Comdex. But several independent sources have already confirmed its existence, so I'm sure we'll be hearing more about it next quarter. I guess this is just one of many topics that you won't find more substantial discussion about, folks who have heard stuff aren't at liberty to repeat it.

Well, I wouldn't doubt John Townsend's post. If you're really being cynical
you might think the usenet poster forged the article, but there's no reason
to have don that, so ...

Geeze. The ST has a 16 bit bus, it doesn't look crippled to me... It's
certainly not going to be as fast as it might have been, but the Falcon is
by no means a crippled system.

(And at any rate, [heh] there's bound to be a 3rd party board that comes
along with a zero-wait 32 bit synchronous RAM expansion. It's definitely
not necessary for the home user, which is what the Falcon is aimed at, but
I'm sure it'll be there for the hobbyist...)

The DSP will allow multiple programs to reside in its memory, but I don't
think (sorry, for the guess, I haven't read the docs lately and I really ought
to have by now...) more than one can be executing at once.
>
>Will this also mean that two assemblers are needed too? One which

Yes, you need a DSP56001 assembler in addition to the 68k assembler if you
want to write for the DSP. There are system calls to transfer 56k object code
from ST RAM into DSP RAM, etc.

As far as I know MultiTOS is not doing swapping, so you don't have to worry
about reaching for a memory location that's been swapped out.

hutch@bellman.lanl.gov (John Hutchinson) writes:

>C'mon folks, let's get real here, OK?

>Personally, I don't give a twit if the Falcon has a 32, 16, 8 or 2-3/4 data
>bus... as long as it performs and performs well in consideration of its cost!

But the point is that a '030 on a 16 bit data bus isn't going to perform
nearly as well as an '030 on a 32 bit bus. The 16 bit bus will affect
almost all aspects of the machines performance. There were rumours that
the 'true colour' modes would cause contention over a 32 bit bus. The
16 bit bus will not improve graphics throughput any.

>That's like saying, I don't like this program because it was written in
>BASIC (or pick your favorite "non-favorite" language). Even though it may be
>the greatest thing since sliced bread you still don't like it? Who cares?

No - it's like saying I don't like this program because it could have
been so much better, and I can see alternatives programs availible which
look better.

The Falcon is not without competition. The A1200 looks considerably
better, simply due to the fact that it is a true 32 machine.

The fact that the Falcon only has a 16 bit bus might not deter people
who own an ST from upgrading to the Falcon, but Atari desperately needs
to attract buyers who would otherwise have purchased a PC. Crippling
the Falcon to reduce the price was not the way to do it.

>Sure, a lower throughput bus probably would limit the _potential_ of the
>machine, but there _are_ considerations that were made for compatability with
>older ST/STe software. You don't have to like it, but be reasonable.

No, these consideration were due to one thing only - cost.
As for compatability, a UK magazine testing games on the Falcon found that
they all worked fine provided they did not use the sound chip.
A grand total of 3 I believe.

>All IMHO, of course. :)

Of course.

Is it really true that it has a 16-bit processor-to-internal-Ram Bus?
I'm asking for this specific bus, not for some card you could put in!
(like small vme). The information that's given here does not exactly
state this. And i can't believe that they really use an 16bit Ram-Bus
in the Falcon..

greetings

thomas

4390. GCC V2.2.2 Errors

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-19 13:43:07 UTC
From: cmh@eng.cam.ac.uk
Message-ID: <1992Nov19.134307.16517@eng.cam.ac.uk>
Source record: 41894

I have a problem installing GCC V2.2.2 on my ST (1040STF expanded to 4Meg, 48Meg HD, TOS 1.2, SM124). I have the two "hello" programs as follows:

```
/* hello.c */
#include <stdio.h>
main()
{
printf("Hello World\n");
return(0);
}
```

```
/* hello.cc */
#include <stream.h>
main()
{
cout << "Hello World\n";
return(0);
}
```

I am invoking the compiler from Gulam, with, as far as I'm aware, the correct environment variables set.

In the first case (hello.c) the program compiles and runs fine (implying that GCCEXEC, GNUINC, TEMP etc are correct).

In the second, the preprocessor executes fine (indicating that GXXINC is OK) but the compiler proper gives several errors of the type:

#-lines entering and leaving files don't match

I believe that all my includes are of the correct patchlevel (GCC pl 80, G++ pl 7), so what's the problem? All the binaries came from a.a.u.e. in the GCC 2.2.2 distribution.

I am sorry for posting this to the net, since it's probably just me being thick, but I have had two very late nights trying to figure this one out.

Thanks in advance for any help (email, or post if of general interest)

Christopher Hicks (cmh@uk.ac.cam.eng)

Source record: 41897

cdw@dcs.ed.ac.uk (Christopher Walton) writes:
: I am considering doing a memory upgrade on my STFM and it will involve
: soldering a socket on top of my shifter. Can anyone tell me how vulnerable
: this chip is as I am not very experienced with a soldering iron ...
:
since the shifter is quite expensive, you should consider to get your
connections from a socket between the old shifter socket and the shifter
itself or from a board whith two pin-lines (?) on the downward and
a socket for the shifter on the upward side, as i did for my memory upgrade.

you probably need to re-bend the shifter's shielding cover then.

of course this won't do if your shifter isn't socketed yet. in this case
i would adwise you to first get some solder on the socket and shifter pins
seperately where they later touch each other. be careful on the shifter,
touching the pins only for 1 sec., allowing them to cool a few seconds
inbetween and work in an nonadjecent order.
so prepared, when you get the socket in place, the iron needs a shorter
time to establish a connection because the solder only has to melt
together and not to coat both surface then, thus less heat for the chip.

and be sure to make the +5V & ground connections thick wires, b/c
memory chips need a high current at peak levels.

I was not being cynical. I was merely hoping that it was not true.
I apologise to Mr Townsend if I implied he was lying.

>Geeze. The ST has a 16 bit bus, it doesn't look crippled to me... It's
>certainly not going to be as fast as it might have been, but the Falcon is
>by no means a crippled system.

Yes, but the ST also has a 16 bit processor. It is not crippled.
The ST also does not have to deal with 16 bit graphics throughput.
The Falcon on the other hand has a 32 bit '030, crammed into a 16 bit
bus, similar to the Mac LCII. As for the Falcon not being crippled, I will
wait to use the machine to see. I have my concerns about the speed of
the graphics over a 16 bit bus, though. 16 bit graphics over a 16 bit
bus, sharing access with the processor does not sound as though it will
be particularly fast.

>(And at any rate, [heh] there's bound to be a 3rd party board that comes

Exactly! What I want to do is to patch her EPROMs with WINX 2.0. It
supports 40 Windows under GEM and minimized slider bars and more! There
is a CPX-Module to configure the new features.
You do not need to patch your ROMs, but it saves memory and loading time
I think. If you have TOS 1.xx simply put WINX.PRG in your AUTO folder.
If you have TOS 2.xx you'll need GEMRAM for copying your GEM into RAM.
If you have a TT look into the WINX documentation: There are some
Utilities recommended.

>So I think I caught you out this time John...

fighting? :-)

>Eproms are 256k 150ns or better...

Can I go to an electronic dealer and ask for 256k (kBit i think) EPROMs with 150ns or better. Won't he ask me for the pin compatibilities to any ROM?

The upper 2 MB of the 16 MB are wasted because the memory-mapped I/O
registers live there. I wonder why they didn't add in a control bit to
bank-switch that last 2 meg in. Oh well.

From: morrison@ee.ualberta.ca
Message-ID: <morrison.722218428@ee.ualberta.ca>
Source record: 41900

Greetings,

I made a similar post on comp.sys.atari.st recently, but it occurred
to me that this group is more appropriate.

Basically, in my 1040 STE I have installed the new TOS 2.06 ROMs but
my system won't operate with them in place. The installation documentation
says that "jumpers W102, W103, and W104 be se to 1-2, 2-3, and 1-2 respect-
ively. I can't do that easily, as my system board has resistors soldered
into those locations--in the configuration 2-3, 2-3, 2-3.

What can/should I do to make my new TOS work?

>minor bug fixes but is there more? Does 2.05 support the 1.44Mb format?
>Just curious so I'll have the right answers the next time.

a) Yes, it'll support READING 1.4MB format.
b) No, it won't support FORMATTING 1.4MB disks.

If you use a SCSI floppy, a driver comes in between, so that it won't
matter which TOS you use (altho >= 1.4 is probably better, for reasons
that have been hashed out FAR too many times with respect to Hard Drives)

4401. GFA Basic Manual Wanted

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-20 06:00:43 UTC
From: matthew@hitech.com.au
Message-ID: <722239236.11245@hitech.com.au>
Source record: 41910

HI !
I got a copy of GFA Basic from a CoverDisk on the magazine ST Format.
The only problem is they gave you a refernece manual on disk but you had to
order the full manual (this was a bit pricey for my budget). So I need to
order a GFA Basic manual from the supplier (whoever that is) or by a secondhand
one (unlikely), or a cheap new one. Any suggestions ?

Thanx,

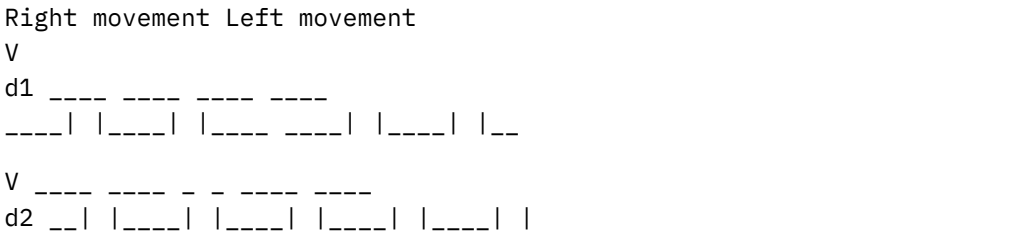
4402. Re: help my mouse won't stop

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-20 06:34:56 UTC
From: marc@targon.UUCP
Message-ID: <2708@targon.UUCP>
Source record: 41905

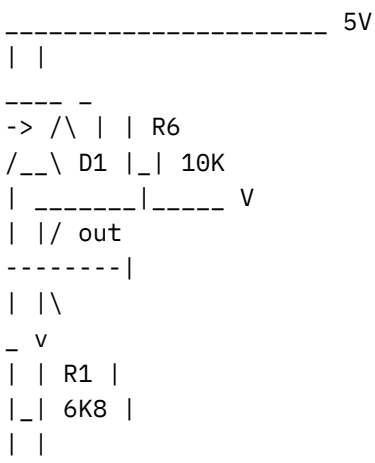
The Dutch magazine 'ST' of July/August 1990 had an article 'Stop
de Genius!' which explains what may be causing the problem of
automatically moving mouse pointers.
I'll try to translate and summarize (in my broken English anyway...)

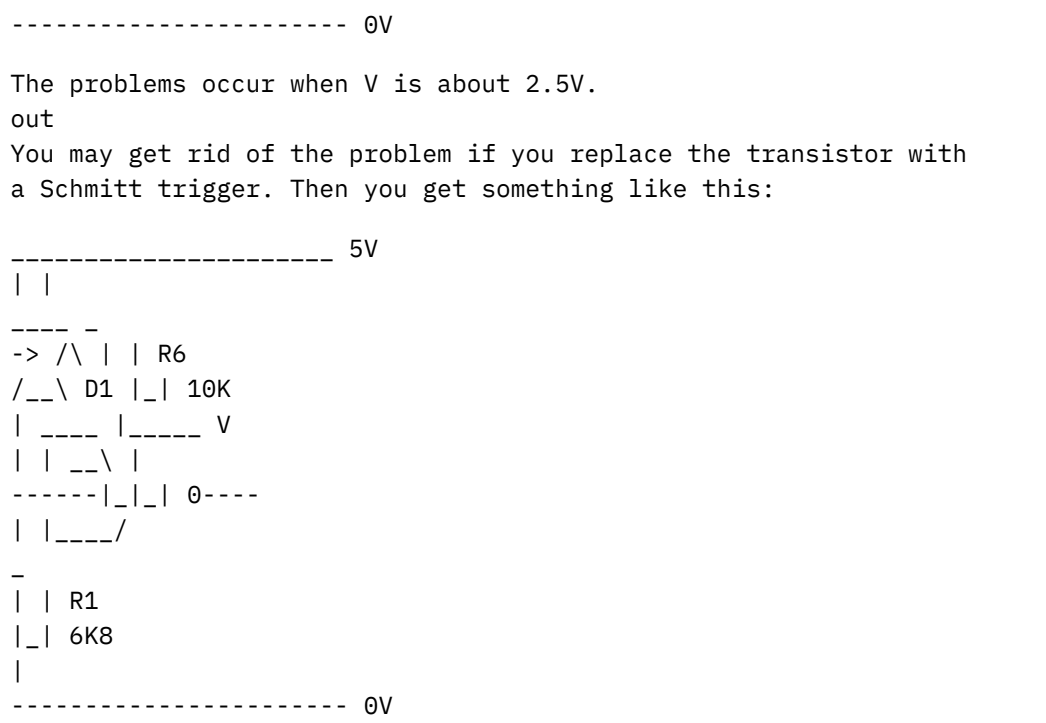
For each direction the mouse has two light sensitive diodes.
These diodes are lit by some light source. Between the light
source and the diode rotates a disk with holes in it.
Depending on the mouse movement, the light sensitive diodes
see a block wave of light pulses. The block waves for the two
diodes are 90 degrees out of phase; thus the direction can be
estimated from the fase difference of these block waves (see figure).



Now the ST reacts to the flipping of one or both of V and V .
d1 d2
The problem would not have occurred when it would have reacted
only when both of the pulses were flipped, but now it is possible
that due to some distortion on one of the signals the mouse pointer
moves in one direction!
It must even be possible to simulate this distortion manually if
you move the mouse just a very little bit. In mice like the Genius
this distortion may be caused by some 50/60Hz noise on the 5V line.

The Genius mouse has for every diode the following circuit:





So all you need is a quad Schmitt Trigger and some solder experience.
Ofcourse you do this on your own risk, I take no responsibility
for damage of whatsoever! (But the people of the 'ST' magazine seem to
know what they are talking about). I have not tried it myself
(no thanks, no Genius mouse for me), so I hope this really helps.
Is this something for the hardware FAQ?

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello,

I am interseted in putting a reSOLUTION SUperVGA card into my 4 meg 1040STF. My entire system is in a tower case so space is not a consideration. I would like to know if anyone has this card card installed in a 1040STF? How east/hard is the installation? I assume it must be a solder in card?

The only distributer that I know of in the US is Rio-Datel, and I was made aware of there shady nature concerning the Lexicor software scame. Does anyone know of any other dealers that may be able to obtain this card for me? By the way the German company that manufactures the card is called "GengTec".

Many thanks,
Scott Kolodzieski

: hutch@bellman.lanl.gov (John Hutchinson) writes:
:
: >C'mon folks, let's get real here, OK?
:
: >Personally, I don't give a twit if the Falcon has a 32, 16, 8 or 2-3/4 data
: >bus... as long as it performs and performs well in consideration of its cost!
:
: But the point is that a '030 on a 16 bit data bus isn't going to perform
: nearly as well as an '030 on a 32 bit bus. The 16 bit bus will affect
: almost all aspects of the machines performance. There were rumours that
: the 'true colour' modes would cause contention over a 32 bit bus. The
: 16 bit bus will not improve graphics throughput any.

Why do people complain about things they haven't even seen? Just because
32 is 2 times 16 it doesn't mean the falcon would be 2 x faster if it had
a 32 bit bus. And the video subsystem DOES have 32 bit access to memory.

: [..]

: The Falcon is not without competition. The A1200 looks considerably
: better, simply due to the fact that it is a true 32 machine.

Just try to compare the A1200 at 640x480x256 with the falcon at the same
speed - the A1200 slows down to the speed of an A500 with that resolution,
while the falcon 030 is about 2.5-3 times faster than a 8MHz ST. Does the
A1200 still look better now? It's no point in discussing and complaining
about the falcon's design if you don't even know how it looks. It's very
cleverly done, IMHO.

: The fact that the Falcon only has a 16 bit bus might not deter people
: who own an ST from upgrading to the Falcon, but Atari desperately needs
: to attract buyers who would otherwise have purchased a PC. Crippling
: the Falcon to reduce the price was not the way to do it.

"Crippling to reduce the price"... hah... If people are so stupid to
think the falcon 030 is slower than an A1200 because it has a 16 bit bus,
they deserve the A1200... :)

: >Sure, a lower throughput bus probably would limit the _potential_ of the
: >machine, but there _are_ considerations that were made for compatability with
: >older ST/STe software. You don't have to like it, but be reasonable.
:
: No, these consideration were due to one thing only - cost.

Yeah, sure! You know better...

: As for compatability, a UK magazine testing games on the Falcon found that
: they all worked fine provided they did not use the sound chip.
: A grand total of 3 I believe.

Hmm... sounds like the usual amiga-(f)lamer-add-on to his posting...

4407. Wanted : GFA Basic Manual

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-20 12:17:45 UTC
From: matthew@hitech.com.au
Message-ID: <722261860.13416@hitech.com.au>
Source record: 41936

Hi out there !
I am looking for a manual for GFA Basic version 3.5. I got my
copy of a CoverDisk from a magazine called ST Format. It included a *short*
reference manual (141 pages approx.) Unfortunately this isn't much help in
the way of BIOS commands, (or much else, for that matter). So I am looking for a
manual either second hand (unlikely I'll find one) or cheap firsthand. Otherwise
I'll order one from the distributor. ANY info at all would be most helpful.

Thanks in advance,
Matthew /|\

>Umm... not much else is there?

If you get a copy of the latest Znet, there's an article from Jim
Allen taken off GEnie that says basically that he's found a way to do
it, but is trying to get info out of Atari, not always the easiest thing
to do, about how the blitter lets the processoror know it's on the bus.
I beleive he found a plug in to SMD adapter, but if the blitter doesn't
communicate properly with the processor, it won't know when the cache
data was invalidated or something like that. Sorry to be vague, but I'm
not really a hardware type. Anyway, dig up Znet, and check out the
letter.
ZNet should be on a.a soon, I wouldn't bother looking for alt.znet,
as from my readings in alt.config, I beleive all US gateways have it x'd
out because of some misunderstandings on it's creation. It sure hasn't
shown up here, and my feed creates every newgroup that comes through.
Anyone in North America see an alt.znet group?

True, it's difficult to predict. Things like prefetching instructions tend make it worse than you might expect. The '040 is an extreme case: running over a relatively slow, 16-bit bus it is SLOWER (much slower even) than a plain 68000. There is no reason I can think of to run the '030 on a 16-bit bus (except to cripple the machine like Apple does), which makes me believe this is just misinformation. But who knows, it's Atari. :)

Good. Too bad that the Falcon is yet another closed Atari box, while C= has managed to put in a decent level of expandability for a low-end machine (PCMCIA plus a -complete- expansion connector for anything from simple fast RAM cards to '030/'040 accelerators).

Yeah - wait until GFA 4.0 comes out and order it... Here's the
address and phone number for Richter, who now makes GFA for the ST.
Until then, the quick reference file is pretty useful (I have 3.0, and
use the doc file constantly while programming, so I don't have to hunt
through a 500-bjillion-page manual).

Richter Distributor,
Hagenerstrasse 65,
5820 Gevelsberg,
Germany.

Phone: + 49 2332 2706
Fax: +49 2332 2703

Hope this helps.

I must disagree. I have 3.05 in my TT (~2.05 in an ST) and after flipping a dip switch (which can be done via a CPX) the "FORMAT FLOPPY" command displays a high-density option along with single sided/double sided. (But unfortunately for me, all this does is make griding noises in my floppy since I don't have a high-density drive :(

Hi, this is just to give some idea of progress in the last week. I've ironed out the main bugs in SETUP (the one that disbled the filesystem!), and I'm left with some in INSTALL which seem not to apply the correct permissions to the files stored on disk.

The main reason for posting, though, is to say that I now *know* that the reason I've got no mail for the last 2 months is the Computer Centre's fault (and I thought it was my feet...). So, if you've mailed me in the last 2 months I've not been ignoring you, I never got your mail.

If you want to get in touch with me, then try the addresses below. I *will* reply (even if to say "got your mail"), so if you don't get a reply I didn't recieve your mail. Could you try one of the other addresses in this case...

1. sjg@dogmatix.ph.kcl.ac.uk (the machine on my desk)
2. sjg@phlim.ph.kcl.ac.uk (the mailserver...)
3. sjg@dsd.bio.ph.ic.ac.uk (the machine at IC where I'm a sysadmin)
4. sjg@star.op.ph.ic.ac.uk (another machine at IC)

If you're on JANET rather than internet, please use...

1. sjg@uk.ac.kcl.ph.ipg

Simon.

Current Notes is a U.S. based Atari magazine which began life years ago as a newsletter for a consortium of Atari user groups in and around the Washington D.C. area. It has evolved into a nice mag with a color, glossy cover and about 80 pages per issue. Perhaps the best thing about it is that it is written by users for users and true to its name, its info is "Current." It's not as classy as ST Format, but you can usually believe what you read in it. :)

Subscription rates in the U.S. are $27 per year; foreign rates are $36/year.

4418. Surface mounted 68030?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-20 21:29:26 UTC
From: wmagro@uiuc.edu
Message-ID: <By1AD5.Kw2@news.cso.uiuc.edu>
Source record: 41919

I've read here that the 68030 in the Falcon is surface mounted. Does anyone know of a good reason for that? Wouldn't it be reasonably cheap and forward thinking to put it in a socket?

<< stuff deleted >>

Mark, there has been a LOT of confusion lately as to the status of GFA BASIC for the Atari platform. I too, thought that Richter had purchased the entire rights to the Atari version but evidently, this is NOT so. Here is an excerpt from a letter by John Barger, Tech Director at GFA Software Tech in Salem, Mass that was in the Nov issue of Current Notes:

"It is important for people to know that GFA-BASIC and GFA Software Technologies, Inc., are here to stay and fully support the Atari market. Said support can be shown in the imminent release of GFA BASIC 3.7 with more new features than you can "shake a joystick at" (including a new GEM-Based editor, a faster compiler, and Falcon/Multi-TOS compatability).

If Richter ever comes out with a 4.0 GFA BASIC with all the features that were rumored/promised in an earlier post here, then that's fine with me. But in the meantime, GFA Software Technologies in the US is still with us.

>the graphics over a 16 bit bus, though. 16 bit graphics over a 16 bit
>bus, sharing access with the processor does not sound as though it will
>be particularly fast.

The memory is 32 bit wide, the CPU <-> memory bus is 16 bit wide but the
videochips <-> memory bus is 32 bit wide! This is WERY similar to the TTs
videomemeory, except that the TTs videomemory is 64 bit wide (YES, i said
64 bit wide, and I have the scematics, so there's no doubt about it) but
the CPU (68030) of course acsesses this memory through a 32 bit wide bus!

>And how do you intend to plug your 32 Ram expansion in?
>The PDS internal slot is 16/24 bit.
>The processor is surface mounted.
>Umm... not much else is there?

The coprocessor socket have the full databus of the 68030, then the problem
would be the address bus, but with soldering only TWO leads directly to the
68030s adresslines and taking the 24 lower addresslines from the expansionbus,
one can have 32MB of Fast-ram. Shouldn't be too hard to do, or what?

>

Are you trying to convince yorself not to buy a Falcon or what?
A1200 more expandable than the falcon?
Oh, well it has to be (though i doubt that it realy is), because it does NOT
have SCSI II, 16 mips DSP, 8 channels of 16Bit/50Khz sound and bultin 16 bit
stereo AD/DA, and is further crippled by a upper limit of only 2MB of
videoram!

The 'new' Amiga 1200 is O N L Y a souped up A600, whilst the Falcon 030
is a totaly new concept in homecomputing!!!

I like development of new abilities better than just speeding up old and
well known abilities, howewer when both are combined, as in Falcon, i realy
get enthusiastic!!

Message-ID: <92325.213059JJL101@psuvm.psu.edu>
Source record: 41924

The main difference between the two TOS's (2.05 and 2.06) is that while
both can will and format 1.44 density disks, only those formatted with 2.06
will be compatible with IBM format 1.44 disks. (of course for 2.05, you could
always just format on a ibm 1.44 and then bring it home to a 2.05 machine to
use it also).

One of the people in the same dept as I work in used to be a
programmer for Fairlight (an Australian company who make high end
music equipment). He said the DSP (MC56001?) can support 8 audio channels
(but I think this is 8 virtual channels which are added to form a stereo
pair). I didn't discuss the matter in depth (so sue me :-).

4425. Does Gulam use TERMCAP?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-21 08:24:38 UTC
From: mike@r-node.gts.org
Message-ID: <1992Nov21.082438.21290@r-node.gts.org>
Source record: 41928

I use Gulam all the time, but only recently have started playing with the terminal emulator. I see in the doc file, there is mention of a termcap emtry, with which the author stated 'we have used this with `vi and `emacs.

If I set the TERMCAP variable to TERMCAP = "d:\termcap", with the file d:\termcap containg the term def, will Gulam actually use it? I tried it, and connected to a dos-ansi system. It wasn't working, ... should it?

4426. Sozobon Help Needed

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-21 22:44:01 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1992Nov21.224401.25052@oz.plymouth.edu>
Source record: 41927

Hello,

I'm having immense trouble linking accs with sozobon. I have one
file that I wrote that I CAN link into a successfully working acc, but
when I tried to modify that code and change the function of the program,
but still using the original base I cannot link. I get a double
definition of __main error from the linker. This is very frustrating,
especially in light of the fact that the original compiles and links
every time. I am using sozoinit.o (changed to dstart.o), because I
cannot seem to make an acc with the original dstart.o at all. Can
somebody shed some light on the problem? Anyone write accs with sozobon?
If so I'd really like to see some code. Basically I took this code
from a very old st-log magazine that featured an accessory. That is how
I found out how to do the original acc stuff.

4427. Hard disk with ADSCSI.....Help!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-22 03:53:24 UTC
From: danieldr@ecr.mu.oz.au
Message-ID: <9232714.23171@mulga.cs.mu.OZ.AU>
Source record: 41929

G'day peoples,

Can someone please help me on the following problem I have with
a hard disk which I am connecting to my 1040STFM with the AdSCSI host adapter.

My hard disk assembly consists of the following.....

1. NEC D3861 SCSI HARD DISK.....130 Mb
2. 200 W P.C power supply.

I have connected all the components together in a PC Case.
And I am confident that all the connections are correct.
Now, when I power up the hard disk and then boot the ICD disk
utilities. I find myself (after about 20 secs.) on a gem desktop with
no disk icons. From here I obviously cannot run the ICD Format program.
I have noticed that the same thing happens when I completely remove
the SCSI cable which links the adapter to the hard disk. (ie just having a
'powered' AdSCSI board connected to the Hard Disk port of the ST. Can
someone check for me if this is normal behaviour ?
So what can be wrong?
One of my prime suspicions is the SCSI cable which I made myself. I
accidently (well didn't read the manual before doing it) connected the red
edge on the cable to pin 50, instead of pin 1. But surely this shouldn't
matter? As the red edge connects to pin 50 on the other end. So all coressponding pins are
connected together.....I think....can someone clarify this?
Another possiblilty is that my hard disk isn't compatible with
the host adapter (unusual I hope) . Or that the hard disk isn't functioning
properly. There are no led's on it.....but apparently it has a self diagnostic
test.
Or maybe it is the AdSCSI host adapter that isn't working ??

Any help would be gratefully appreciated.
Thanks.

Daniel.

Ah... I was not aware of this (I don't get any ST mags right now...
and since I'm not on DELPHI right now, c.s.a.s is my main source of ST
news right now)... Is there a review of GFA 3.7? I'd like to keep
straight compatibility with the DOS/Windows/Amiga (and someday Mac and
OS/2) versions... The C-translator is a great concept, if it works right
(I'd rather code some stuff in C, and the current compiler is a pain to
do that with).

A feature comparison would be cool when they both come out... Any
volunteers in net-land?

>blitting, i.e.\ blit n-1 of the entries (n=no of items in scroll window)
>and write out the new line either at the top or bottom of the

I've been thinking about that as well, surely this is an often-enough used bit of code that someone has published a standard way to do it... My approach was simply to create a box, then create a bunch of string objects as children of the box. Scrolling the text in the box is then only a matter of changing the string pointers and calling objc_draw to redraw the box.

>list. And what is the best strategy to write a smooth moving slider which
>will sit next to the list box? I have managed to write a relatively
>smooth moving slider but it's not perfect.

Did you already look at graf_slidebox in the AES? Probably a lot easier...

That little note describes a termcap entry that you can use on a Unix box to drive the Gulam screen, which is just the standard Atari screen control characters. Most folks call this setup "st52" because it is a superset of the VT52 controls.

Nope. Gulam knows nothing about termcap. Quite a pity. At some point I'm definitely going to have to recompile the thing; I use it too much to let it go like this...

So you do have sources???

If this is true, are they available somewhere?

So far, everyone complains about this and that concerning Gulam, but
noone has hands on sources. This is somewhat a pity, since there are a
lot of things, that simply have to be corrected (shell_p, fixed screen
size etc.)

Cost. I advocated bank-switching the extra 2 meg during the later
stages of the Falcon030 design, but it turned out that it would have
been tough to do for a reasonable cost. Re-layout of boards, already
multiplexing bits on the memory controller, etc. etc.

p>> >OK, here's an easy one. Someone asked me the other day what the
p>differences
p>> >between TOS 2.05 and 2.06 were. I understood there were just a couple of

TOS 2.06 will run on non-STE-machines, whereas 2.05 does not. Also, Atari added some minor features like visible RAM-test on bootup (with nice Atari logo), <Alternate>-<num keypad> entry of any ASCII value.
TOS 2.05 works fine for 1.44meg drives, although only TOS 2.06 installs a _FDC cookie. So, the only drawback for 1.44meg floppies on TOS 2.05 is that other programs than the desktop will not recognize the 1.44meg capability of the machine. (This is only important if that program wishes to format a disk, though. Reading and writing is done by GEMDOS and BIOS, of course.)

4434. GFA: Compiled program bombs at SWAP *x%,x$()

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-22 14:55:50 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1eo71mINN1889@rs1.rrz.Uni-Koeln.DE>
Source record: 41935

Hi tech folks,

I have run into an annoying problem with the GFA basic 3.6TT system. The command mentioned in the subject causes the compiled program to exit with two bombs, or sometimes to exit wit an "Error 64" alert box. However, in the interpreter the program runs without such a problem.
This takes place on a TT, in TT med resolution, no matter whether the TT ram bits are set or not.
I have tried to write a short program that reliably reproduces the error, without success. Therefore, I include an outline of what I do in the program that causes the trouble:
The program is GEM-based and menu driven. It loads stuff from files into string arrays, and this stuff can then be displayed in windows. There can be several windows, which can all be redrawn by the same routine. Therefore, I chose to store the the pointer to the array which is shown in a window in some window-specific, MALLOC()'ed chunk of memory. When it comes to redrawing, the redraw routine retrieves the pointer, called p_st%, from the memory. It creates a dummy array, swaps the pointers, draws the window acessing the dummy array which is the real array because of the swapping. When redrawing is done, the arrays are swapped again and the dummy array is erased. In GFA code, that is:

```
PROCEDURE redraw(w_handle&,x&,y&,w&,h&)
LOCAL p_st%, ...
DIM d$(0)
a%=@w_adr(w_handle) !determine pointer to window-specific stuff
p_st%={a%+176}
~FORM_ALERT(1,"[1]["+STR$(p_st%)+"|"+str$(*stb$())+"][ Ok ]")
SWAP *p_st%,d$()
.
. (redraw the stuff)
.
SWAP *p_st%,d$()
ERASE d$()
RETURN
```

The alert box reveals that p_st% and *stb$() are identical, so the problem is not that GFA basic has shuffled the array around and the pointer once stored is no longer pointing to the current location of the array descriptor.
Unfortunately, it doesn't seem to be possible to write a function for swapping arrays manually. The problem is, swapping seems to swap the internal pointers to the array descriptors rather than

the descriptors themselves. But maybe, I'll have to work on this. I'll post to the net if I can find the reasons for the problem or ways to work around it anyway.

BTW, a while ago someone mentioned he had a list of known GFA bugs. I'd appreciate if this could be mailed to me.

Thanx in advance

Greetinx, Jan

Ok,

I've just read the f30.zoo file from Atari.Archive and
it sounds great (with the exception of 1040 case, how are they
going to fit it all in?) It was old, but stated the Falcon 030
would be available in US in Mid-october, but I certainly haven't
heard a confirmation of that. When will it be released? And hw
accessable with it be (ie. how many will be made?) Anybody
at Atari ever release anything on time? Not that I've ever
found, but it would be nice if they could get it in gear.

4438. Falcon Spec's [per Comdex handouts]

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 00:32:56 UTC
From: grr@cbmvax.commodore.com
Message-ID: <37222@cbmvax.commodore.com>
Source record: 41940

This is from the Falcon literature handed out at COMDEX - any transcription errors may be due to my receiving a "D" in typing class a few years back.

Please note that there are one or two items in here which there might be quibbles about - the 32/32-bit spec apparently being for the processor and not the system and calling 640*480/262144 colors "Super VGA"...

****

Atari Falcon030 Specificiations

System Architecture

o CPU: Motorola 68030 operation at 16 MHz.
o On-chip demand-paged memory management.
o Separate on-chip 256-byte instruction and data caches.
o Independent address and data buses for increased performance.
o Pipelined architecture.
o BUS: 32-bit data, 32-bit address.
o FPU: Optinal Motorola 68881/2 operating at 16 MHz.
o RAM: 1, 4, or 14 MB configurations.
o ROM: 512 KByte internal; 128 KByte external cardtrige.

Digital Signal Processor

o Motorola 560001 DSP operating at 32 MHz.
o 16 MIPS perofrmance at 32 MHz.
o 32 KWords of 0 wait-state static RAM.
o DSP conenctor allows easy connection of low-cost fax/data modems, voice mail systems, direct-to-disk digital audio recorders.

Expansion Bus

o inernal direct processor slot for 286, 386 and 486SX processor boards to run DOS and Windows(tm) applications, DMA coprocessors, etc.

Graphics

o Super VGA: 640x480 256 colors.
o True color 16-bit mode; allows display of up to 65536 colors.
o Accepts external video sync signal to allow high-quality genocking.
o Overlay-mode for easy video titling and special effects.
o Optional overscan.
o 262,144 possible colors.
o Hardware-assisted horizontal fine scrolling.

o BLiTTER(tm) graphics coprocessor.

Sound

o Eight 16-bit digital audio DMA record and playback channels with
up to 50 KHz sampling rate.
o Stereo 16-bit digital DMA audio output.
o Stereo 16-bit digital DMA audio input.
o SDMA sound/DMA coprocessor.

Standard Ports

o SCSI II port with Direct Memory Access (DMA).
o High-speed LocalTalk(tm)-compatible LAN port.
o Connecor for VGA, composite vidoe, RF, or broadcast analog RBG.
o Bi-directional parallel printer port (also suitable for
image scanners).
o Cartridge Port (128K-byte capacity).
o MIDI IN / MIDI OUT.
o Stereo microphone input: miniature stereo plug.
o Stereo audio out: miniature stereo plug.
o Two 9-pin joystick connectors.
o Two 15-pin enhanced digital/analog controller and light-pen
connectors.

Data Storage

o 1.44 Mbyte floppy disk drive.
o MS-DOS(r) formt compatibility.
o Optional internal IDE hard drive.

User Interface

o Standard QWERTY keyboard layout, Low profile, sculptured
ergonomic design.
o 94 keys; 10 function keys.
o Separate numeric and cursor keypads.
o Keyboard processor to reduce CPU overhead.
o 2-button mouse supplied as standard.

System Software

o Pre-emptive multitasking with adaptive prioritization (MultiTOS).
o Inter-process communcation through multiTOS messages and pipes.
o TOS in ROM.
o Hierarchical file system with sub-directories and pathnames.
o Icon-based graphical user interface, with self-explanatory
command functions.
o On-line help.
o Multip window user interface with icons and drop-down menus.
o NewDesk(tm) desktop and extensible Control panel allows
customization by user.

4439. GNU CC compiler - configured for 68000

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 01:21:09 UTC
From: nrossi@jarthur.claremont.edu
Message-ID: <1992Nov23.012109.24827@muddcs.claremont.edu>
Source record: 41841

I was referred to this newsgroup in search of a C compiler for the IBM
which can produce machine code for the 68000. I need such a beast for
a microcontroller board I'm working on which is based on the 68000.
I was told that some folks over here have configured the Gnu-CC compiler
to produce 68000 code. Is there an FTP site where I could get my hands
on this 68000-configured C compiler?

Thanks,

Nick

4440. Re: GFA Basic graphics routines

[...]

>PLEASE TELL ME THIS: Is there a compiler for GFA 3.0 ???

Yes.

>If so where do I get it? And, where could I find a manual for just the compiler
>on earlier versions. I bought a bunch of software from a guy, I got 3.0 in the
>box with manual. And an earlier version, but no manual. I am writting a cool
>game program, and everything was going fine, then all of a sudden I was unable
>to compile it. My work has screeched to a stop because of this!!

Regarding getting a working version of the compiler, the
situation seems to be kinda unclear these days, as Richter is
continuing the ST version of GFA basic, but GFA themselves maybe
too... at any rate, the best advice I can think of is contact
either Richter or GFA. One of them should be able to inform you
about the compiler.
Another possibility may be, try to update to GFA basic 3.5. The
update price should be moderate, and it's worth it anyway.
Sorry, I don't have any addresses handy right now, but both the
GFA address and Richter's address used to be around in other
postings these days...

>I want to finish this program, I already have 100 hours into it, several sound
>samples, and lots of work with Degas.

Wish you good luck and lots of fun!

>Also, another question while we are on the subject:

>Is there any source code out there (GFA) that will play digitized samples and
>leave the os free to do other things while these samples play?

I never did anything like that myself, but I'm sure you
absolutely can't do a background sample player in GFA for the
plain old ST. Getting arbitrary samples out of the PSG requires
exceedingly fast and well-timed loops and can therefore only be
done in assembly language. The newer Ataris (STe and TT) that
have DMA sound are another matter, but still, if you want to have
CPU time for other purposes, assembly language is the way to go.

4441. Re: GFA: SWAP *x%,x$() problem worked around

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 02:05:37 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1epe9hINN1oc8@rs1.rrz.Uni-Koeln.DE>
Source record: 41843

In <1eo71mINN1889@rs1.rrz.Uni-Koeln.DE> aeg03@rrz.uni-koeln.de (Jan T. Kim) writes:

[description of trouble deleted]

One more observation: GFA seems to fail to keep track what data types are stored in which area. The result of

```
PRINT TYPE(*stb$())
```

is -1, which is supposed to indicate that the passed pointer does not point to any valid data type. However, it should be 5 (for pointer to an array of strings). I still don't know what's going wrong, but then, that's Richter's or GFA's business...

>Unfortunately, it doesn't seem to be possible to write a function
>for swapping arrays manually. The problem is, swapping seems to
>swap the internal pointers to the array descriptors rather than
>the descriptors themselves. But maybe, I'll have to work on this.
>I'll post to the net if I can find the reasons for the problem or
>ways to work around it anyway.

Today, I don't see what made me post that a working around the problem by swapping the array descriptors won't work. I found that it works perfectly. Instead of the swap command, you can use:

```
PROCEDURE swapstrarr(VAR p_x%,y$())
LOCAL p_y%,arrbase_x%,arrbase_y%,anzdim_x&,anzdim_y&
p_y%=*y$()
arrbase_x%={p_x%}
anzdim_x&=INT{p_x%+4}
arrbase_y%={p_y%}
anzdim_y&=INT{p_y%+4}
SWAP arrbase_x%,arrbase_y%
SWAP anzdim_x&,anzdim_y&
{p_x%}=arrbase_x%
INT{p_x%+4}=anzdim_x&
PRINT {p_x%+4},anzdim_x&
{p_y%}=arrbase_y%
INT{p_y%+4}=anzdim_y&
RETURN
```

At least, this seems to do the trick for me now.

4442. The Falcon Bus Thing..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 02:45:03 UTC
From: Colin.Toal@nautical.r-node.gts.org
Message-ID: <1992Nov22.214503.26367@r-node.gts.org>
Source record: 41845

Okay, from my limited knowledge of the situation and what I have read from the folks at Atari, someone said (I am not sure if it was Jim Allen->Fast Tech or Bill Rehbock) that 16 bit Data Bus was done to ensure ST compatibility, and that it would be easy to upgrade to 32-bit Ram using the Ram Expansion Connector in the Falcon. The DaughterBoard Falcon Ram essentially gives you another Expansion port, and 32 Bit Ram can be placed in here to increase '030 performance. Claiming the Falcon is crippled because it is 16 bit Data bus is silly. I think a major reason it was done was because having the CPU on a 16 bit Data Bus and the VIDEL on a 32-bit Bus would relieve any possibilities of Contention. Hopefully in the Falcon040, they will have a 040 32 Bit Data Bus and a 64 Bit VIDEL Bus (like TT Video Ram).. Out of Curiosity, the TT also has a split bus with ST Ram being 16 bit and TT Ram being 32 bit.

> I've read here that the 68030 in the Falcon is surface mounted. Does
> anyone know of a good reason for that? Wouldn't it be reasonably cheap
> and forward thinking to put it in a socket?

Not really. When you use surface mount components, you cut down
on the number of individual components required to assemble the Falcon
and the number of seperate assembly operations. This makes the process
of making Falcons (or any other electronic equipment) faster and cheaper.
Surface mount also tends to be more reliable (the drawback is that when
a surface mount component is faulty, it's more expensive to repair or
replace it). Fewer warrantee repairs mean more satisfied customers and
lower operating costs for Atari.

I can see that a socketed 030 would let you add Page Mode 32 bit
ram by plugging a ram board into the 030 socket and the 030 on top of the
ram board, but Atari seem to have other priorities.

What do you mean by real-time ?
JPEG in real-time is not so easy (unless working on VERY small images,
or slow animation). Specialized hardware can do it, but it involves
some tricks (the C-Cube chip is told to use more than 200 pipelining
levels to achieve a 1MB to 25MB decompression per second).

Oh, well, anyway, the output stream can't be much more than 1MB/s so this
could be the limiting factor (10 100k images/s).

4446. VGA monitor on 1040STf

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 09:31:50 UTC
From: laverman@cs.rug.nl
Message-ID: <1992Nov23.093150.20135@cs.rug.nl>
Source record: 41850

I subscribed to c.s.a.st.tech just for this question, so sorry if it is
an old one. (wasn't here the last 5 days, but anyways)

I have an 1040STf, with next to it an Olivetti PCS286. The olivetti
has a VGA color monitor, so naturally I'm wondering about getting the
color tube on the atari. I could buy an off the shelf cable, but that
would cost me allmost a 100 Dutch guilders, which is more than I
can afford at the moment.
Anyone have a diagram on how to connect this? any pitfalls? dangers?

Greetings, Bert

4447. ICD host adapter info

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 11:58:26 UTC
From: rh0083b@medtronic.COM
Message-ID: <1992Nov23.115826.17491@medtron.medtronic.com>
Source record: 41852

Hello Atari gurus!

I have an ICD Advantage Plus ST host adapter in my ST disk system. I want to develop a driver for a tape drive, but I have no documentation of the host adapter (I do have the tape drive's OEM manual).

Does anybody have such documentation? Where can I get it? Or order a manual?

Specifically I am interested in:
- how does the ICD host adapter handle SCSI messages?
- how can I generate a SCSI reset without messing up the ST system?
My guess is that I cannot use the RST instruction...

Note: I live in The Netherlands (Europe), so European ordering info is preferred!

Thanks in advance,
-Roger

4448. Gem programming

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 12:19:23 UTC
From: richard@star.ic.ac.uk
Message-ID: <1992Nov23.121923.16446@sol.ctr.columbia.edu>
Source record: 41849

Some of these questions might have been floating around a couple of months
ago, but I've forgotten the solutions, so...

1) NEWTOP message: This can be used to disable scroll bars when sent to
a window which is about to be deactivated. Does it work? I mean does
multitos/gem send this message to an applications top window which isn't
the desktops top window? Also is there a simple command to disable
scroll bars or should I just set the slider size to 1000 and ignore any
scroll messages not sent to the top window. Some people might think I
should leave the bars active - but I learnt to program gui's on a mac,
and scroll bars in the active window only is the convention used. This
makes sense since a click in a deactiveated window only has one operation...
to bring it to the top... how can you scroll something you can't see??
Obviously on large screens you can have windows next to each other - but
most macs and st's don't have these.

2) Bezier curves. (I think): I'd like to be able to produce cirlces
ellipses, etc. using curves with dragable handles. I've seen this done
with four curves per circle etc. (a) is v_pline the
best way to draw them (lots of points in array for definition) and (b)
(not really gem but...) what's the equation/algorithm for these curves.

3) Menus: There was an argument going on about which key to use to cycle
windows... (can some one mail me the standard key bindings for menu
options??) Something I've seen and like is a list of an applications
open windows in a menu, selecting the item brings that window to the top.
What's the best way to implement these "growing menus"? I could have a load
of blank entries and change the text as required - but that's ugly, or
possibly a user defined object, but that'd highlight wrong. The only other
solution I can think of is to copy the menu tree, and change it on the fly,
this would involve keeping track of the box which contains all the items
as well as farting about with the object pointers to allow more space for the
new line. Is there an easy way to do this??

4) Key bindings: I was using ORCS and noticed a "key..." button in some of
the editing windows. Playing about with this (I've only ever had access to
"mkrsc" before, so I don't know how standard this is), I've discovered that
bits in the type and state fields of the object structure are set to represent
the modifiers and key press (extra numbered bits at bottom of lists).
A small routine can process a key press by
comparing relevant bits in the key varaibles returned from event_multi
and the fields in all the objects in the menu tree. When a match is found
you know you've got the right item... but is the item a child of the title???
Of course not, so what's the best way of finding an items title...
(another mac hang over - my menu handler requires title and item). I've got

one method, but it requires that the titles be in order. Not very flexible. Obviously the same key bits could be used to add the short hand text to each menu item at the time the resource is loaded, is there a standard way of doing this and what is the normal character used to denote <ALT> in a menu item? This method will save any arguments on which key bindings are best since you can just change them if you don't like what you're given.

If you're still reading, thanks for your interest, now post/mail replies, even if they're not code related but just your point of view on scroll bars etc.

Since I've spent the last three hours catching up with last weeks news, I'd better get down to some work... maybe a quick rescan first.

Richard

[... message deleted ...]

Actually, it sounds like you are at the perfect place to run ICDs hard disk formatter. The first thing that the program will show you is all of the devices it can find. It will display the name of the device next to the SCSI ID. Since it obtains the name from the devices itself will be testing your cable at that time.

Unless this drive was formatted on an ST/STe/TT you most likely will not get a hard drive icon until you have formatted and partitioned the drive.

Again it sounds like you need to run the formatting program to start verifying your setup.

> Ta!

The 68030 has a flexible bus architecture. It can happily live on
an 8 bit, 16 bit or 32 bit bus.

The 68040 requires a 32 bit bus, unless the design team wants to add
a lot of hardware to do it. :^(

4455. MiNT distribution version 2.0

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 19:58:30 UTC
From: sjg@phwoof.ph.kcl.ac.uk
Message-ID: <1992Nov23.195830@phwoof.ph.kcl.ac.uk>
Source record: 41858

Hi,
Well, after lots of late-night hacking (I've fallen out with virtually everybody in our house!), I've got a set of 9 disks that I've put in the ftp-able dir.

You'll find them in the pub/MiNT directory, with documentation (a PostScript file) in Docs/, the disks themselves in Distribution/, and an atari, a Sun, and a Dec binary of Zoo in Zoo/

This is the first release of this set, so there are almost certainly some problems that need to be sorted out. If you feel brave, or if you fancy helping me out, please have a go at installing it. I need some feedback as to how I should go about improving it. I got *no* mail back about the last kit, (though I think that was more to do with my mail being screwed at the time), so any info gratefully recieved.

If you do want to mail me, then the address that seems to work is ...

sjg@phlim.ph.kcl.ac.uk

although the address of preference (which ought to be working RSN) is

sjg@dogmatix.ph.kcl.ac.uk

Simon.

4456. Re: MiNT distribution version 2.0

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-23 21:46:22 UTC
From: sjg@phwoof.ph.kcl.ac.uk
Message-ID: <1992Nov23.214622@phwoof.ph.kcl.ac.uk>
Source record: 41859

Whoops. Suppose I'd better tell you all where the machine with the ftp service is

It's actually at dogmatix.ph.kcl.ac.uk

Sorry about that,

Simon.

>Just curious so I'll have the right answers the next time.

You do not need any serial patch for the RTS/CTS bug in earlier
TOS Versions!

Question: Does anybody use TURBOCTS with the MUPFEL CLI? With the
TURBOCTS in the AUTO folder, MUPFEL doesn't execute any command?! The
problem was fixed using RS232ENC from the RUFUS package. But why?

Hello,

Thanks to everyone who replied about compiling ACCs with
Sozobon.
I had in fact been using sozo 2.0, but am now using 1.33, it is
much better. I have not compiled an ACC yet, but I can tell from
the better workings of the GEM stuff I've been doing that I
should have no trouble with 1.33.

: : simple fast RAM cards to '030/'040 accelerators).
: :
: PCMCIA? What's that? Some kind of standard? I don't think so.

Yes, PCMCIA is a standard. It is used for plug-n-play modems, fax cards,
NFS lan cards, RAM, etc for lap-top computers. IBM, Apple, HP, Amstrad, Sharp
and a plethora of other portable clone makers support this standard.

: The Falcon at least has a built-in SCSI-2 connector, which you have to
: pay for if you want to use even plain SCSI drives, as well as a
: "-complete- expansion connector", whatever you mean by that.

If you're talking about the processor direct slot on the Falcon, it's not
a "-complete- expansion connector" in the sense it's only 16bit where as
the Amiga 1200 slot is 32 bits and a bit more flexible with regards to
peripherals attached.

As for SCSI-2, yes it would be nice on the Amiga1200. The 2.5" IDE connector
is okay for home use as most people don't need more than two hard-drive.

: / Joern F. Moe / All above is my own personal opinion! \

From someone who seems to speaking with inside information and works at
Atari, you seem very rude or ignorant. This type of marketing reminds me
of the Amiga 1000 vs Atari 520 arguments. Atari tried to sell itself by
making all sorts of extravagant claims or hide that their machine does even
more poorly without this feature. Like the blitter steals processor speed,
(wheras the processor has to do all the work on the ST), interlace flicker (in
screen modes that the ST didn't have), we don't need a pre-emptive multitasking
operating system (something you still don't have)... etc...

If you compare the posts from staff at Commodore to Atari, we see that the
Commodore people are much more diplomatic...

Regards,

Jim Fang

The sound hardware in the Falcon can use one of three different clocks - 32MHz, 25 MHz, or external clock input. Additionally, the clock can be divided down by one of about 16 different standard prescale values. This is what's given in the standard sound system calls. However, it seems that the built-in codec is only allowed to be used with the 25 MHz clock. I don't know why that is... It's not a problem for the DSP, though. Regardless, the codec supports more speeds than just 12.5, 25 and 50 khz, those are just the common speeds that were also supported on the STe.

As long as this is going to be a topic of discussion, please remember that there are several independent elements of the Falcon audio system that can be interconnected in a variety of ways. You can use all, some, or none of them as you see fit. In fact there are so many different elements available it's difficult to choose where to start, in a system description.

You have the codec with stereo 16-bit ADC and DAC, DMA record channels, DMA playback channels, external inputs and outputs, etc. The codec's ADC can be connected to the mic input or to the Yamaha PSG output. (Independent left and right channel control there.) You can independently activate any of the 4 stereo audio tracks, and select any one of those tracks to be monitored by the internal speaker/DAC/stereo headphone jack. You can record or playback in any of 8-bit mono, 8-bit stereo, or 16-bit stereo. At system bootup I believe the ADC gets both channels from the PSG, and everything else is bypassed. For the voicemail software that I wrote (that was running all week at Comdex) on the Falcon, I had the audio matrix connecting the ADC to the

DMA record channels, using only a single track. For the next version I'll have the ADC feeding the DSP, do some compression in the DSP, and feed the DSP output to the DMA record channel instead. The Falcon audio system is incredibly flexible, I only need to add two system calls to my existing code to add this functionality. (Oh, and load my compression routine into the DSP, but that's really a separate issue. That's the total impact on my code, tho.)

One of the quirks I've noted is that the PSG doesn't have a hardwired connection to the speaker, and the system bell and keyclick are still generated there. If you have sound software that wants to record thru the microphone input, those system sounds disappear (unless you only set one channel to the mic, and leave one channel for the PSG...).

Yes i have done it, but I would not recommend it to you as you do not
seem to be aware of the problem.
A CGA monitor is TTL input, an Atari computer is Analog output. You need
to make an analog to digital converter to connect them. There was a
circuit published in Elector a few years ago to do this, but I found it
needed extensive modification to be acceptable. Overall it was not worth
the effort. I now use a multisync, but that's another story. The sound
output on the Atari will not drive a speaker directly. Use an amplified
speaker of the type available for
walkmans.

Source record: 41867
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello,

It seems that the only viable solution to getting enhanced graphics in my ST tower system is to replace my 1040ST motherboard with one from an old Mega, thus giving me a MegaBus expansion slot. This seems like a good option but the tower case I have is manufactured by a German company called LightHouse and it is designed for a 1040/520.

Does anyone out there know how the 1040ST motherboard compares with the Mega ST motherboard? Some key questions,

1. Are the external (rear) connectors of a 1040 and a Mega in the same locations on the motherboard.

2. Are the two motherboards the same size.

3. Does a Mega motherboard have the same plug in connector on it for its keyboard that the 1040 has. On the motherboard of a 1040 there is a small connector that consists of a number of pins sticking staight out of the motherboard vertically, that a keyboard cable pushes down on.

Many thanks,
Scott Kolodzieski.

MiNT does install a cookie. The following function (by ers himself) stores
MiNT's version number into the global variable __mint.

```
extern int __mint;

static void getMINT()
{
long *cookie;

cookie = *((long **)0x5a0L;
if( !cookie )
__mint = 0;
else
{
while( *cookie )
{
if( *cookie == 0x4d694e54L )
{
__mint = (int) cookie[1];
return;
}
cookie += 2;
}
}
__mint = 0;
return;
}
```

Using only fixed sampling frequencies is no drawback whatsoever. If you look at resent samplers, you will notice that many of them use fixed sampling rates. The reason is that if you use variable sampling rates, for instance to change the pitch of your sampler, you will need very sofisticated DA conversion techniques with accurately ajustable output filters to avoid alias distortion.

Changing the pitch of a sampled sound (and stretching or shrinking its length along with it) is very easy, and can be pretty accurate if you use some quadratic interpolation techniques. The same ideas apply to sample rate conversion: with a bit of interpolation you will get along quite well.
Changing the pitch without changing the length, or the other way around, is much harder. But that is not any simpler on variable sample rate architectures.

4470. Atari: TOS 2.06 -> STE (not)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-24 14:24:23 UTC
From: rgoseweh@digi.lonestar.org
Message-ID: <1992Nov24.142423.8667@digi.lonestar.org>
Source record: 41876

You are gonna find this one interesting:

My 1040STE is at Atari for service work. (Atari and I are currently carrying on a dialog about whether or not the machine is under warranty and what is wrong with it. It is in because the internal drive fails to reliably track beyond track 68 or so - appears to me to be a mechanical drive problem.)

Anyhow, the Atari service rep that called me says that the TOS 2.06 ROMs do not belong in an STE. (It was working perfectly fine for me for approximately 6 months or so. :-) He went on to say that their engineers couldn't figure out how it was working, that 2.06 only goes in a MegaSTE, and that the only ROM upgrade for a 1040STE is *2.07* (which I have never heard of).

Really gives me a warm, fuzzy feeling about the capability of the hands that are going to care for my machine. :-(

4471. V.32bis modems and ST/Spectre

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-24 15:06:18 UTC
From: jthomas@kolanut.mitre.org
Message-ID: <1992Nov24.150618.21821@linus.mitre.org>
Source record: 41873

Has anyone had any experience using V.32bis (14,400 bps) modems with the ST either in ST or Spectre Mac emulation mode? Is the serial port fast enough to handle the data at full speed (I know a standard IBM's serial port is not). Does the ST handle Xon/Xoff signaling correctly? Does Spectre? Does any ST or Mac FAX software work?

I'm probably going to get either a Supra or a Zoom. Zoom has the slight price advantage. Any advice?

Joe

A CGA monitor is TTL input, an Atari computer is Analog output. You need
to make an analog to digital converter to connect them. There was a

Source record: 41874

Well on the STFM at least the trick is too 'fool' the video chip into drawing more than it was supposed to by 'at the right time' flicking between 50 and 60hz display.

When I set this up originally I found that there were two possible display types, we could have just extra display at the bottom and the top stays at the normal position, or the top could be expanded as well giving around 34 rows instead of the normal 25.

The problem is that the timing is a little critical so in addition to using something like timer B I found I had to check from the current screen write address which area was currently being traced.

Anyway I expect it is a little different on an STe, but after writing a game in this 'bigscreen' mode it was awful to come back to a standard size desktop. My best attempt at setting up a bigscreen that ran in the background taking minimal CPU time still just about noticably slowed things down - the problem was that if I cut things too tight then I ran the risk of 'missing' the critical point and everything hung, and the other problem is of course that damn keyboard chip losing data on the way through, if it was interupted by the timer.

Still do any STe owners out there know anything more about this?

Mark

4474. Fonts and Font editors

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-24 17:35:28 UTC
From: jmb8302@cs.tamu.edu
Message-ID: <1etp50INNfs3@tamsun.tamu.edu>
Source record: 41875

I've tried to make and load up my own fonts for a program that I am making but all I get are bombs. I've used the regular GDOS and AMCGDOS plus different font editors(FONTZ! FED etc) but no luck. Are there any font editors out there that actually work? Also, could someone post the address for the low and med res font location? One more thing, there must be a way to hardcode a font into a program, how is this done?

thanks in advance

From: jensk@hpbbn.bbn.hp.com
Message-ID: <JENSK.92Nov24104523@hpbeo82.bbn.hp.com>
Source record: 41881

The termcap entries in the Gulam manual are meant for using Gulam as a terminal
emulator (i.e., wou would put them in the *other* computer's termcap file).
Gulam itself doesn't use termcap.

>The variable sample rate in the Amiga is one of those things that
>is intended to minimize memory/computational requirements when
>used with a simple DAC scheme, but given a farily powerful DSP,
>there are other ways of getting the same job done.

The 12.5,25,50KHz rates are what the DMA sound subsystem can record/playback at, they have nothing to do with the sample rate of the PCM sample you are trying to play. Sound Blaster cards have 11kHz sampling rates, and Sound Blaster Pro cards have 22kHz sampling rates. No one sees this as a limitation.

What the DSP chip will need to do is run an algorithm to change a sample from rate XkHz to a rate the Atari dma sound subsystem can play. These algorithms range from disgutingly simple to amazingly complex depending upon the desired quality, and how close the original sample rate is to the desired sample rate.

And unless I read incorrectly the DMA sound subsystem can accept an external clock to play at rates that are not STe/TT compatible.

Source record: 41878

Ok people, I guess I got it wrong again.

This one will work. Trust me. I'm almost a doctor!

The ftp machine is NOT (as I said in the last post) dogmatix.ph.kcl.ac.uk - I typed my own machine name instead of - it is phlim.ph.kcl.ac.uk.

The machine will NOT be available for ftp (even I can't get at it) for the next 24 hours. We've just taken delivery of some new DECstation 5000/133's (one of which is mine :-)))) so the system is just recovering. The data disk will (unfortunately) be the last thing to be put onto the network, so I would wait until about 4.00 British time until you try and ftp the stuff.

In answer to the questions I've received by email,

1. yes I will put it on a.a but since I can't get at it yet, I'll do it asap.
2. My internet email address swill change to (hopefully this one will work) sjg@unhygienix.ph.kcl.ac.uk OR sjg@phlem.ph.kcl.ac.uk
These are the same machine. If you have problems getting through, then it probably hasn't filtered through to you yet. In this case, please try the sjg@phlam.ph.kcl.ac.uk - which people have been mailing me at recently, so I know it works.
3. The TT-specific code I will try to integrate asap. I haven't got a TT, so I can't test it, but if it is similar to the ST stuff, there ought to be no problems...
(crosses fingers)

Simon - hoping that THIS time he's got it right....

>as wide as the "crippled" falcon.

Get seriouse! The falcon have 14Meg of 'videoram'. How then can you figure
out that the A1200 with only 2 Meg have 2 Meg more than 14Meg???????

And in 4 months (their own estimate), GE soft will have a 32Bit fastram
upgrade ready for the falcon 030 for those who need the speed. The 6030
in the Falcon have ful external 32 bit bus. Theoreticaly you could
upgrade to ~4GB, but in the A1200 (EC020) there will be a maximum of
16MB because of the limited 24 bit addressbus.

And before you start talking about cripled bus on the F030; do you know
ANYTHING about the TIMING and SHARING of the bus in EITHER of the F030
and A1200?? I know a bit about the F030, but nothing on th A1200.

>: I like development of new abilities better than just speeding up old and
>: well known abilities, howewer when both are combined, as in Falcon, i realy
>: get enthusiastic!!
>:
>I do to. The only evolutionary things I see on the falcon is the dsp. This
>coupled with the sound chips and processors will allows for some really good
>music and effects generation.

The DSP is a part of the sound subsystem. The sound subsystem is a 8 channel,
16 bit, 50kHz DMA-driven recording system. The DSP 'just' adds realtime
manipulating capabilities of the sound. The DSP can work on non sound related
tasks while the sound DMA takes care of playing sound. So the whole sound
subsystem is quite evolutionary, not only the DSP. Name any homecomputer at
under 1000$ that have CD quality 16bit sound.....

4479. Micropolis Hard disk drive - help !

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-24 21:03:40 UTC
From: geoffc@zebedee.uucp
Message-ID: <H.1sqnrhhONfE@zebedee.uucp>
Source record: 41884
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Can anyone help me get a hard disk drive I have recently acquired working.
The drive is a Micropolis 330Mb Half-height drive, Model no 1684-7
manufactured in 1988.

On the back of the hard disk drive is the power connection, the SCSI
connection and 12 jumper connections. On the circuit board by the
jumper connections are labelled:

<nothing> ID1 ID2 <nothing> TP3 <nothing> .... <P4>

The drive spins up OK but the ICD software doesn't recognise the drive
as being present on the bus at all - I know I have the SCSI cable in
the correct way around because the ICD clock is there OK.

The only instructions I have are for setting the SCSI address which involves
putting jumpers accross the first 3 connections in various combinations.
I've got no jumpers on so it should be SCSI ID 0. The drive does have the
terminating resistor pack in OK.

I have tried putting jumpers in the TP3 and 24 positions but the drive still
wasn't recognised.

I know the drive is OK because it used to work OK on a friends PC.

I suspect that I need to change the parity setting but I don't know which
one it is - any ideas or can someone give me contact details for Micropolis
(preferably in the UK)

AdvThanks

Geoffrey

>I am considering doing a memory upgrade on my STFM and it will involve
>soldering a socket on top of my shifter. Can anyone tell me how vulnerable
>this chip is as I am not very experienced with a soldering iron ...

I would not recommend this - it can be done, when using ESD
precautions, but there is a much easier way:

get one 40-pin IC socket (the better ones which the round contacts)
and solder the wires to the thicker part of the pins on the bottom
side of the socket. This can be done in a way so that you can insert
this socket between the shifter and the ST pcb, with the benefit that
it can be easily removed and that the shifter is still exchangeable
if it should fail some time.

Or is the problem that your shifter is not socketed ?

cu

4481. (IBM) 1.44 drives - am I silly or what??

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-24 21:22:21 UTC
From: wsbusr3@rw6.urc.tue.nl
Message-ID: <wsbusr3.722640141@rw6.urc.tue.nl>
Source record: 41754

Hi ST - boys & girls,

I've got a major problem with my 1040ST's internal 720K drive.
It's broke.

It has rumour that most internal IBM-drives can replace it
effortless - with some modifications to the ST's cover that is.

So I tried a TEAC 1.44 (internal) drive.
Without a HD-kit an/or different controller it would act like a 720K-
drive, and I could always upgrade it later with a kit/controller.
So I'm told by several people.

<CLICK> ST ON
TEAC 1.44 drive starts spinning, yet fails to read my 720K bootfloppy.
After 30 sec's the dektop shows up anyhow.
The drive simply continues spinning !! (without reading anything.)
<CLICK> ST OFF
I tried the same with the big black connector upside-down
(as was the power-connector, so "who knows..", I figured)
The drive then didn't do a thing, though. (which was better than
exploding in my face, ofcourse).

QUESTIONS:

* My dealer offered me to try his Mitsumi 1.44 and Y-E-Data 1.44
drives as well. If they don't do the job,
I'll get a 80% refund :-(.
Will they be any good?
What brands usually would?

* Can a 1.44 plugged into the ST as is indeed perform like a 720K drive?

* The black connector is way to the right compared to my ST-drive.
Should I solve this with more flat-cable?
Are those cables available with pins on one end,
and holes on the other?
(otherwise I can't even build those drives in properly)

* These IBM-drives are also 1/2 an inch lower than the usual
internal ST-drive.
How does one normally go about building them in neatly?

Suggestions, shared experiences, solutions and sheer laughter
with respect to some, most or all of these 4 questions
please to this group or else to: at073@cleveland.freenet.edu

Thanks in advance!

Already regretting this IBM-drives circus,
cheers,

Rowdy Blokland,
The Netherlands.

>enough to handle the data at full speed (I know a standard IBM's serial
>port is not). Does the ST handle Xon/Xoff signaling correctly? Does
>Spectre? Does any ST or Mac FAX software work?

The Spectre and the ST both work fine with 19200 baud at the serial
port. The MEGA STE is able to use 38400 on Serial 1(?). 19200 will work
fine with packed data and V.32bis/V.42bis and ZModem.
The Mac Terminal program ZTerm (the only one I know) is often to slow
for the 19200 and 'eats' data in Terminal Mode (not during ul/dl). 9600
is recommended then and before using ZModem you can increase the rate.
Type '+++', switch your serial port to 19200 and type 'ato'.

Fax Software is available for the ST. QFax/Pro and Junior Office for
example work fine. I don't know of any PD/Shareware fax program for the
ST. I was never interested in fax programms running with Spectre, sorry.

>I'm probably going to get either a Supra or a Zoom. Zoom has the slight
>price advantage. Any advice?

I'm *very* happy with my ZyXEL U-1496 E! If you are able to connect to
another ZyXEL you can connect at 16800/V.42bis. Maybe the ZyXEL plus
will be the best deal now, because it will support V.fast (28800). Just
take a look in comp.scom.modems!

Scott Kolodzieski asked:

>1. Are the external (rear) connectors of a 1040 and a Mega in the same
> locations on the motherboard.

No.. every model Atari has ever released has been different.

>2. Are the two motherboards the same size.

No.. the 1040 motherboard is the full width of the integrated CPU/keyboard case, while the Mega ST is several inches narrower.. actually, the Mega ST motherboard looks like it would fit in a mini-tower case much easier.

>3. Does a Mega motherboard have the same plug in connector on it for its
> keyboard that the 1040 has.

Yes.. I believe the later ST models all had the same internal connector to the keyboard (six or so connections versus something like 16 in the original 520ST)

Sorry.. there's no easy answer for upgrading an ST...

Hmm. I'm pretty sure some people at Comdex saw 250M 2.5" ide drives. They're pretty pricey compared to the 3.5" equivalent. But you do pay a premium for cutting edge technology rather than last years new-toys.

IDE components are mainly for portables, where small size and lower power consumption are a top priority.

Just one question. Is this SCSI-2 hard-drive and tape-drive meant to fit inside the falcon?

For anyone who'd like a good look at just what a DSP *is*, and what kinds of things it can do, there's a very nice overview in the November 1992 issue of Byte Magazine.

Real world examples of existing and announced hardware and software utilizing various models of DSPs are given, as well as some background about the capabilities (and shortcomings) of DSPs in general.

Several manufacturers are mentioned specifically as having DSP products already available, or announced for "RSN" release, with one particular computer company conspicuous by its absence from the article.

The Amiga 1200 has 2 megs of chip ram. This memory is the only portion of
memory where the graphic and sound co-processors can read and write information
from.

If you have fast ram, the processor will run programs excusively from this
area if you wish. This means if you have a large graphic screen with a lot of
bit-planes, the graphic processor may require more than one cycle to complete
an operation. So as long as the main-processor has some of its own memory
it will continute operating asynchronously.

Can the falcon's main processor and graphics processor operate at the same time
and have access to memory.

From: wilsont@rahul.net
Message-ID: <By9G0I.6rF@rahul.net>
Source record: 41886

With all the talk in c.s.a.st about how poor the original compiler for
TOS was... why isn't there a say... 2.09 version or something
(one that runs in all machines), compiled with a good compiler?

was 2.06 _just_ a new desktop, and a minor serial port fix?

does atari's TOS dev directory look like this?:

gemdos.o 23452 11-04-85
bios.o 14522 10-09-85
vdi.o 32450 02-09-85
newdesk.o 45234 07-05-90
misc.o 32304 04-30-87

Darek M. was saying that a simple recompile of VDI could speed stuff up 10-15
percent. (using a good compiler)

is this not physically possible?

how about 4.0?

: Ok friends! I've seen many demos that are able to fill the entire
: screen with graphics. What is the secret to doing this in software?

In a nutshell, software overscan is done by fooling the MMU
into thinking that it should not stop sending video data although
the standard 200/400 raster lines already have been displayed.
Try toggling the external sync and screen refresh rate bits at the end
of the last regular raster line; with the correct timing, this
opens up the lower border. Similar things can be done for the
upper border and even for the left and right borders. Opening
the left and right borders, however, is a very time-consuming trick.

In comp.sys.atari.st.tech you write:

> I've tried to make and load up my own fonts for a program that I am
> making but all I get are bombs. I've used the regular GDOS and AMCGDOS
> plus different font editors(FONTZ! FED etc) but no luck. Are there any
> font editors out there that actually work? Also, could someone post the
> address for the low and med res font location? One more thing, there
> must be a way to hardcode a font into a program, how is this done?

I've incorporated fonts succesfully in C programs using FED fonts.
One of the output options of the FED font editor ("fontedit.arc" on
atari.archive.umich.edu) is to emit C code containing the offset
tables and bitmap descriptions of the font.

I've included the source of font.c which defines two functions:

```
function description
-------------------------------------------
loadfont() loads a font
restore_font() restores previous font
```

The function loadfont() checks the resolution to decide on the font.
To keep this message brief I've deleted many lines in both the offset
table and bitmap table.

Some questions by myself:
1. I've noticed that the notion of the previous font is not always
correct as it seems. Is the restore code incorrect or should I
get the current font address in a different way?
2. Any additional info on font editors and/or loading of fonts will
be greatly appreciated.

kind regards,
Jan van der Steen

jornmoe@fredrik.atari.no (Joern Moe) writes:

>In <1992Nov24.011541.22871@monu6.cc.monash.edu.au>, William Fang writes:
>>Well, thats two more megs of video ram than the Falcon, and the bus is twice
>>as wide as the "crippled" falcon.

>Get seriouse! The falcon have 14Meg of 'videoram'. How then can you figure
>out that the A1200 with only 2 Meg have 2 Meg more than 14Meg???????

I agree that Mr Fang was quite wrong on the Falcon's video memory, but
having 14 Mb is not strictly an advantage, given that the Falcon uses a
shared bus between processor and video.

>And in 4 months (their own estimate), GE soft will have a 32Bit fastram
>upgrade ready for the falcon 030 for those who need the speed. The 6030
>in the Falcon have ful external 32 bit bus. Theoreticaly you could
>upgrade to ~4GB, but in the A1200 (EC020) there will be a maximum of
>16MB because of the limited 24 bit addressbus.

Fast ram? As in ram only the processor can access? Good - It ought to
speed the Falcon up a bit. I am still curious as to how the 030 will
have 32 bit access to this ram though. Given that the 030 only has 16
bit access to the rest of the system, the only option I can see is to
remove the (surface mounted) processor. The suggestion about plugging
the memory into the maths coprocessor socket was interesting, but the
030 would still only have 16 bit access.

>And before you start talking about cripled bus on the F030; do you know
>ANYTHING about the TIMING and SHARING of the bus in EITHER of the F030
>and A1200?? I know a bit about the F030, but nothing on th A1200.

I know a little about both. The Falcon has no provision for processor
only memory, which the processor can access no matter what the custom
chips may be doing. The A1200 does, though it is shipped without any.
An 68ec020 with full 32 bit access to memory will out perform a 68030
with only 16 bit access. This has been the case on the Apple Macs which
use 030's with a 16 bit bus, and is a proven fact.

Either system without any fast ram will suffer in performance as
graphically intensive screen modes are used, as the processor will be
able to access memory far less frequently. A system with fast ram
however will not suffer.

Those who think that the processor 16 bit bus will reduce contention in
graphically intensive situation are very much mistaken. The 030 in the
Falcon will have to access memory twice as often than if it ran on a 32
bit bus, given that it will have to make 2 16 bit accesses to memory

rather than being able to make 1 32 bit access. This could hamper
things a little in 'graphically intensive situations'.

: use 030's with a 16 bit bus, and is a proven fact.

An 68EC020 however can only address a MAXIMUM of 16 Mb RAM, it can NOT
provide virtual memory (like the 68030 with built-in PMMU) so you will
never be able to use more than 16Mb of memory! The Falcon will be
able to use any amount of virtual memory up to 4 Gb. In my opinion, the
A1200 is seriously crippled, since it is limited to only 16Mb.

: Either system without any fast ram will suffer in performance as
: graphically intensive screen modes are used, as the processor will be
: able to access memory far less frequently. A system with fast ram
: however will not suffer.

Wrong. Since the Falcon has separate buses for CPU and video system
memory accesses, graphically intensive modes will not even slow the
Falcon down to half its speed - The A1200 has been said to stand
STILL at 640x480x256...

: Name any homecomputer at under 1000$ that have CD quality 16bit sound
: and a processor with a 32 bit data bus?
:
: The Falcons sound is it's strength and I can see it doing very well,
: But there is more to any personal computer than a good sound chip.

Yes, for example virtual memory, 16 bit/pixel graphics (I won't even call
it True Colour), GEM, a lot of software (which still runs, as opposed to
the A1200), D/A and A/D converters (this is NOT part of the sound chip)...
And last but not least the DSP which is capable of much more than just
realtime sound effects - for example video phones, software modems with
integrated FAX, and of course serious number-crunching...

-MY

Source record: 41793
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello. we're using Timeworks DataManager ST on a 1040 STf.
We've run out of room for records at 3000, saving to a single
DS floppy. So we bought a hard drive.

Question is:
Will the 1 meg of memory be the next limit?
Is there a way to combine two data files w/ same format?

Your answers appreciated if you have experience w/ TDM-ST. No
guesses, please.

thanx in advance. Please reply email to lch3e@virginia.edu

4496. Atari STFM - Blitterised?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-25 17:04:18 UTC
From: amh15@cus.cam.ac.uk
Message-ID: <1992Nov25.170418.21079@infodev.cam.ac.uk>
Source record: 41795

This is probably a bit banal for this forum, but does anyone know whether the STFM ever had a blitter at any time during its life (as standard)? As I understand it, the STE's main advances were the blitter, new TOS, and large palette, and my parents' STFM from 1988-9 has no blitter. Yet a friend of mine swears that his earlier STFM with single-sided FD drive has a blitter as standard. Can we put this straight please?

(e-mail preferred!)

4497. Omikron+TOS1.0 = troubles?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-25 17:11:30 UTC
From: hjv@phil.ruu.nl
Message-ID: <hjv.722711490@groucho.phil.ruu.nl>
Source record: 41794

I wrote a program in Omikron basic (yeah... I switched to C since then :)
which runs OK on all STs and STEs -- except for machines with TOS 1.0.
Leaving the program gives a 10-bomb crash when returning in the desktop
(= line-A exception), the file-selector has serious problems, etc.
The program uses Omikron's GEMLIB and is a full GEM program. Compiled
with the Omikron compiler v3.0 (I think)

Anybody experienced the same problems? Anybody any clues, workarounds,
patches for TOS 1.0, suggestions of any kind, etc., etc...
I know nothing about TOS 1.0 and don't have it either (fortunately :).
Any help, comments or whatever appreciated, either thru email or in
this group (which I read daily).

Thanks in advance,
Hendrik "glad I moved to C" Jan

No, the 68030 and the 68881/68882 have full databus between them.
That is: all 32bits of the 030 is directly wired to the coprocessor socket,
this is why a fastram upgrade will (probably) be easy to implement.

>>I remember C= claiming to have 3 coprocessors in the Amiga(s), and I was a bit

>Well, that is in your opinion. Others may vary.

If you accept the videoshifter in the Amiga to be a coprocessor, then also the
videoshifter in the ST must qualify as a coprocessor.....

4499. Sozobon dLibs 1.2 realloc() bug...help!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-25 18:50:06 UTC
From: dickia@rpi.edu
Message-ID: <DICKIA.92Nov25135006@aix02.rpi.edu>
Source record: 41797

Hey -

Does anyone know of a bug in the dLibs 1.2 realloc() routine?
It seems to choke intermitently in a program I'm writing... I call the
routine and it never returns -- the machine doesn't crash, it just
hangs.

Part of the problem may be that I'm not casting the types
correctly that I'm passing. The docs I have say it is defined as:

char *realloc(char *ptr, unsigned int *size)

but I've actaully had more success passing signed int's and long's for
the size. Different castings have had different results.

Anyone know anything about this? I'm using TOS 1.0, if that's
any help...

It's weird... the program I'm trying to compile has compiled and run
just fine on about three different Unix platforms.. ugh!

Help!

4500. inquiry: "Matix Datensystem-Germany"

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-25 19:57:35 UTC
From: skolodzieski@vaxc.stevens-tech.edu
Message-ID: <1992Nov25.145735.1@vaxc.stevens-tech.edu>
Source record: 41798
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello World,

I found after much inquiriy that I cannot put a mega motherboard into my 1040-designed tower case. The reason I wanted this is so that I would have a megabus slot to add a third party graphics card to my system. Well I also found out that one can add a megabus to a 1040 via JRI's FPU upgrade, but a number of people that I have spoken with (all extremely competent hardware guru's), have told me that the megabus added this way works only marginally and cannot be trusted to fully function.

Rio/Datel advertised the reSOLUTION graphics card for a plain 1040, but alas I have found that it is not yet (maybe never will be) produced. So the only option that I see right now that does not require me to buy a new mega STE or TT (this would mean scraping a most incredible Tower Case!) is a graphics card manufactured in germany that is supposedly made for the original ST's.

This graphics card if manufactured by "Matrix Datensystem" and is called the "C32 board" it supposedly does 800x600 in 256 colors. Ideally I would like a resolution of 1280x1024 (i don't care if it is monochrome), but 800x600 would be acceptable.

If there is anyone who has any experience with this card or company could you please pass some information my way. They apparently have over 15 different graphics cards for the ST. I have not found one place in the US that stocks these cards. Perhaps a kind german could give them a call and find out about thereselection of graphics cards for stock ST's, I am sure that there are other interested parties besides myself in the US. If they have someone who would not mind a call from a ignorant american who only speaks english, then I would be happy to call them myself, but again I do not have a number for them.

Thanks to all the folks who responed to my ealiar posts about the megaST Motherboard, and Megabuss inquiries. If I get some information on these graphics cards my "Matrix Datensystem" I will post to the net.

Cheers,
Scott J Kolodzieski

Aaaaaaggggggghhhh! Twenty or thirty posts back in this
thread John Hutchinson wrote:

>C'mon folks, let's get real here, OK?
>
>Personally, I don't give a twit if the Falcon has a 32, 16, 8 or 2-3/4 data
>bus... as long as it performs and performs well in consideration of its cost!

Now there's some sense! "Modern" hardware has reached the point
where, save some ray-tracing fanatics and power-hungry collectors,
any machine is capable of doing just about anything you could
possibly want a home computer for. I perceive the latest trend
of "gotta be faster, gotta be bigger, gotta be at the absolute
cutting edge of technology" to simply be a way of running away
from real problem: poorly designed software which doesn't do
what you want.

The Falcon will be a damn good machine if some developers jump
on it and come out with some Really Great Software. That's the
bottom line.

But back to the techno-quibbling.

I've got my hands to ADAPTEC A4000 SCSI-MFM adapter that
allows MFM hard disks to be used with a SCSI controller
and I'm willing to use it with my ST. Atari has quite
SCSI-like hard disk connector called ASCI - am I right?
If yes, can anyone tell what kind of cable I should
build between ST's 23-pin connector and SCSI-plug?

My native language is finnish so please forgive spelling errors etc.

From the Holy Book of <DICKIA.92Nov25135006@aix02.rpi.edu>
as spake by dickia@rpi.edu (Andrew B. Dickinson) :

> Part of the problem may be that I'm not casting the types
>correctly that I'm passing. The docs I have say it is defined as:

> char *realloc(char *ptr, unsigned int *size)

Yow! That's way wrong. What you want is:

char *realloc(char *ptr, unsigned int size)

or better, if dLibs 1.2 supports it:

char *realloc(char *ptr, size_t size)

[of course, you can't actually use these prototypes, unless there's
something Ian hasn't told us ;)]

BTW, what version of Sozobon are you using? If it's not 1.33i, you
should _seriously_ consider upgrading. Look for
/atari/Languages/sozo133i.zoo at atari.archive.

Pretty pointless question - of course not. Point is, how are you going to
hook up a SCSI Tape Drive to your A1200? You seem to think that SCSI is
only for Hard drives, with your "most people don't need more than two
hard-drives" statement.

I am VERY glad the Falcon has a SCSI port. Most Amiga owners will admit
that not having a SCSI port on the A1200 is a MAJOR failing, especially
since the A3000 has one.

> port is not). Does the ST handle Xon/Xoff signaling correctly?

v32bis and v32 can be made to work fine on an ST/STe etc., but you have to get the utility TURBOCTS 1.32 or SERIALFX 1.1. These fix bugs in various Atari ROMS in handling the RTS/CTS handshaking required for high-speed modems. You have to use RTS/CTS for high-speed, XON/XOFF is no good (can cause overrun problems at high speed). You have to realize how high speed modems work, you set your serial port as fast as it can go (19.2K on a regular ST/STe) and the modem<->computer side will go at that speed. The modem<->modem side will go at 14.4K for v32bis. The modem can use real-time compression to get faster than 14.4K on the modem<->computer side. In fact if you could set the computer side to 38.4K there are types of files you could transmit that could cause actual throughput at this speed.

The Spectre is another story. As far as I can tell XON/XOFF works fine under Spectre, I've used Zterm and Red Ryder at 2400 bps. But high-speed modems screw up completely under Spectre. I posted a question about this a while ago and got no replies. I was unable to get TURBOCTS to work when in Mac mode, which I assume is the problem. Anyway, using Flash 1.6 in ST mode is so much faster than anything you could run in Mac mode, why bother? There are ways of downloading Mac software in ST mode, and then transferring it into Mac mode. That's what I do.

> I'm probably going to get either a Supra or a Zoom. Zoom has the slight
> price advantage. Any advice?

The Supra's are very popular and seem very reliable. I've used them, we have several at work.

> Does any ST or Mac FAX software work?

ST FAX software, yes. I think there's a package called Straight Fax that works well with Supra modems.

Well, what you need is a hostadaptor. It converts the SCSI to ACSI, wich is not compatible. (god knows why Atari made it so)

There is a good adaptor around that ICD sells that's called The Link.
I have unfortunatley no information where you can get hold of one. Maybe my fellow netters can supply that information for you. :)

It is a "complete" connector in the sense that it has jast as wide (I
should say narrow) a databus as the processor. Not much use in giving the
expansion slot 32 bits when there are only 16 available.

> : shared bus between processor and video.
>
> The Falcon does NOT use a shared bus between processor and video!
> How many times does this have to be said???

Please elucidate!

Both the Amiga and the traditional Atari ST design timeshare the display RAM between the processor and video accesses. For 68000 7/8 MHz systems, this can be done (nearly) transparently depending on the video bandwidth required, since the 68000 cycles are typically twice as long as that required for DRAM access.

This transparency is typically lost as you go to 68020/68030 processors, since running these processors with no-wait states requires a memory cycle time 3/8's that of the slower processors. DRAM technology simply hasn't mproved enough to allow random cycle times this short.

So, unless there is some very efficient access to the display RAM for the video subsystem, there will be contention between the processor and the display accesses. If there is a separate bus for RAM expansion and other processor activities then is possible to attain higher performance.

So far, I've several different stories about the Falcon video bus and display subsystem, most of which are probably confusion. On one hand, people are asserting that there isn't a shared bus and on the other, they are asserting that all 14M-byte of RAM on the Falcon can be used for dipslay memory. Unless there is some kind of configurable bank switching, this seems to offer a contradiction. It may be that the processor and diplay busses are separate, but leave the question open as to whether you have also have expansion memory that isn't subject to display access contention.

If you can answer the following questions:

1) What is the basis for sharing display memory between the processor and the display subsytem.

2) How many clocks are memory access to the the display memory.

3) Is there or is there not provision for adding expansion memory
that is not shared or display memory?

4) If so, how the expansion space partitioned? Is it really up to
14 M-byte of display memory or is there some split?

> : I know a little about both. The Falcon has no provision for processor

> able to use any amount of virtual memory up to 4 Gb. In my opinion, the
> A1200 is seriously crippled, since it is limited to only 16Mb.

You may be missing the point that the A1200 expansion connector has full
access to the system internals and it is a trivial excercise to implement
an expansion board that includes a 68030. It is not much harder to do
one which would incorporate a >> 14/16 MHz processor. Such a board would
probably also include fast memory tightly coupled to the processor which
would provide much higher performance than the base unit.

As a result, the 16M-byte limitation and lack of VM support you cite
are not architectural limitations, the are simply features that, while
not included in the base unit, can be added via expansion provisions.

More questions:

1) Are there really 32-bit addresses carried between the processor
and the expansion memory connector, or either only 24-bits
or some pre-multiplexed addresses?

2) Is there decoding of the high order 8 address bits or other
for distinguishing the > 16 M-byte space from the = 16M byte
space nominally supported by the system archtecture?

3) Does the memory expansion provide a full 32-bit databus, or is
it limited to the 16-bit system/processor bus?

4) Can memory cycles on the RAM expansion be faster than the shared
display memory or is the memory control logic and timing
in common between the two?

4) Is the ROM 16-bits or 24-bits?

5) Is there any connector for adding a "processor expansion"
connector that gives accesses to full 32-bit adddress and
32-bit data busses?

I would point out that the Atari COMDEX spec sheet makes no mention at
all of a "memory expansion" connector, only an expansion port said to

support x86 compatibility boards. According to postings here, this
connector seems to say that it is only 24-bit addresss, 16-bit data.

> : Either system without any fast ram will suffer in performance as

> : able to access memory far less frequently. A system with fast ram
> : however will not suffer.
>
> Wrong. Since the Falcon has separate buses for CPU and video system
> memory accesses, graphically intensive modes will not even slow the
> Falcon down to half its speed - The A1200 has been said to stand
> STILL at 640x480x256...

Non-interlaced, 640*480*256 will slow down the A1200 considerably -
interlaced or with some intermediate number of bit-planes, far less so.
With the addition of some fast memory expansion, there would be little
overall processor slow-down, though there would still be contention
when accessing display memory.

1) How much does 640*480*256 non-interlaced slow down the Falcon?

2) Is there any relief available for the "graphically intense"
modes that make the Falcon "stand STILL"?

Another factor not really mentioned is how much access to display
memory is required to animate the display of typical games. The
8 64-bit sprites in the A1200 and their hardware prioritization
with one 256-color or two 16-color "playfields" can implement many
game displays with less byte-bashing than the Falcon "dumb frame
buffer" video subsystem.

> : Name any homecomputer at under 1000$ that have CD quality 16bit sound
> : and a processor with a 32 bit data bus?
> :
> : The Falcons sound is it's strength and I can see it doing very well,
> : But there is more to any personal computer than a good sound chip.

I would point out here that the A1200 has two possible expansion
points for adding DSP/16-bit sound. One is the industry-standard
PCMCIA port, which lends itself to DSP's which use the SRAM buffer
model used by the Falcon. It is also possible to add a DSP via
the processor expansion slot, which would provide full/width high
bandwidth access to the DSP subsystem, which could also be a bus
master.

> Yes, for example virtual memory, 16 bit/pixel graphics (I won't even call
> it True Colour)

1) What resolutions are supported by the 16 bit/pixel graphics?

2) Is it true that the 16-bit/pixel mode slows down the Falcon to a crawl?

Though the HAM-8 mode isn't "true-color", the 1280*480 HAM-8 interlaced
display mode effectively provides a 420*480 image with 18 bits of

arbitrary color per-pixel, and gets better where gradual shading of
real-world images allows the base-register/color-increment nature of
HAM to come into play.

While 16-bit "true-color" is a step beyond the 256 color modes, it
will be interesting to see how A1200 HAM-8 images compare to the
Falcon images.

I shouldn't even mention the Falcon's 18-bit palette vs. the A1200's
24-bit palette, but...

Also, there are those hardware sprites, which still operate in the
HAM mode and can be manipulated to provide either 8 independent
64-bit overlay images of placed end-to-end for up to 512 bit wide
overlay graphics - up to the full screen length of course.

And the ability to change resolution and video mode in mid-screen
in system-supported, user-control ways, which allows the user to mix
graphics and text displays on the same monitor, transparent to the
software involved.

> .., GEM, a lot of software (which still runs, as opposed to
> the A1200), D/A and A/D converters (this is NOT part of the sound chip)...
> And last but not least the DSP which is capable of much more than just
> realtime sound effects - for example video phones, software modems with
> integrated FAX, and of course serious number-crunching...

With respect to your other points:

1) Has Atari made any noises about supporting VM in Multi-TOS? It's
kind of pointless to boast a feature for which there is no
system/software support.

2) GEM...

3) "Most Software" runs on the A1200. The software that doesn't is
exactly the same class of stuff that will either die on the
Falcon or take no advantage of the new capabilities of the
system - namely the cheap Game software that ignores the OS
and manipulates the hardware directly.

4) DSP - all of the things you mention are possibilities, but so far
DSP's seem to serve mostly as audio-output engines and the
rest is all either un-realized potential or things that work
better when you buy a "black box" and plug it in.

> PS: Will this discussion ever end?

I could aplogize for getting technical, but I have a certain degree
of knowledge about the A1200 internals. Some of the questions raised
above are sincere requests for information, since I have no access
to a Falcon or the developer documentation, others are intended more
to prick at some of the assertions or contradictory claims made by
Falcon adherents.

A while back, I might have admitted that the Falcon would give the A1200 (as it comes out of the box) some competition performance-wise, but the 16-bit memory makes me wonder. I can state that the A1200 expansion provisions allow it to transcend the somewhat limited capabilities included, but it isn't clear if this is also true of the Falcon.

The Falcon does have some nice features built-in, notably the SCSI port, the 16-bit sound/DSP system, and (maybe) the LocalTalk port, but I think that these capbilities can all be added via the A1200 expansion provisions if the user needs them, and in some cases the add-on expansion will provide better solutions - a PCMCIA Etherent adapter would be more useful (for me) than an Apple'ish LocalTalk port.

It should also stand for something that the A1200 has a big-brother, already shippping, the A4000. This *68040* system is available today, and while highly compatible with the A1200 and other Amiga's offers a multi-slot expansion bus, 2 M-bytes of display memory and up to 16 M-bytes of fast memory (SIMMS) on the motherboard, with available memory cards providing at least 64 M-bytes memory per card.

Of course the 68881 socket has only a half-dozen address lines connected
to it, so if it is the *only* place that the other 16 data-lines are available,
it will make for interesting devices.

Are they also present on a memory expansion connector and are "all 32"
address lines also on a memory expansion connector?

> videoshifter in the ST must qualify as a coprocessor.....

These terms are arguable. I've never seen the Amiga "video shifter" called
a co-processor and wouldn't argue that it was one even though it contains
far more "intelligence" than the Atari equivalent. Sprites, Playfields
and Collision detect logic are non-trivial...

The Amiga chipset does contain several co-procesors/DMA engines of varying
degrees of intelligence:

1) Blitter - this is a data manipulation engine, not stored program but
operates on masses of data after setup by the processor.

2) Copper - this is a beam synchonous processor, with a stored program but
with rather limited data manipulation capbilites - it can load
Amgia chip registers controlling (among others) display formats

and the color lookup table.

3) Sprites - stored program and data, though the program amounts to little more than the control bits for each sprite and it's position.

4) Audio and Video - these are basically sequencers to establish a flow of data to their respective output devices, complex but with no real intelligence.

5) Floppy - similar to Audio and Video.

The first three of these could be considered as co-processors since they operate largely independent of the processor and perform task that would otherwise require processor activity or intervention. The others might be better described as "DMA channels", though they are a bit more sophisticated that that might suggest.

|With all the talk in c.s.a.st about how poor the original compiler for
|TOS was... why isn't there a say... 2.09 version or something
|(one that runs in all machines), compiled with a good compiler?

The main limiting factor is engineer-hours. There's a lot of weird code
in the guts of the OS that relies on compiler-specific things.
Significant progress has been made, in that by now, all of the AES and
Desktop have been rewritten with compiler portability in mind. A big
problem for the VDI and BIOS is that every assembler available for the
ST uses different syntax for different features.

Incidentally, Falcon TOS has a new GEMDOS which was compiled using
the Lattice compiler. The resulting code is considerably tighter
and faster than the older Alcyon-generated GEMDOS. And, of course,
the multitasking kernel will most definitely not be Alcyon-compiled.

4518. More than 4mb on ST !?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-26 11:27:12 UTC
From: ebeling@theo.physik.uni-bremen.de
Message-ID: <ebeling.5.0@theo.physik.uni-bremen.de>
Source record: 41814

I have an idea how to get more than 4 mb meomory on a conventional ST, that I would like to share with the ST community. Maybe I don't know some details about the ST memory system and someone can tell me if I am completely wrong.

The idea is the following: If the GLUE chip does not recognize an adress above 4 MB, because he doesn't see A22 and counts on during startup, the GLUE would count 8 MB memory.
Now the MMU needs to adress above 4 MB using Ras,Cas etc.. With a GAL logic swichting to the higher 4 MB bank, if A22 is high, it should be possible to put additional 4MB in the system.

Sounds like a very simple idea, it must be wrong, but why ?????

There are as far as I know two ways to get more than 4 MB in the ST.
One is using the ADDMEM instruction of TOS 2.06 and put some more memory on an VME bus card, which is supposed to be not a good way of doing it.
A second way is to use a additional MMU that was devolped in Austria and let this chip do the work of addressing memory above 4 MB. The chip is very expensive ($450), but seems to deliver a clean way to get more memory without using the VME bus.

With all the multitasking ideas around, there is an need to get more than 4 MB on the ST machines. So everybody with ideas about a hardware realisation of more memory in an ST should write about it in this group. Maybe we are able to find a way.

Now don't tell me to buy a Falcon to get more memory. I haven't seen one and I bought my MEGA STE 1 year ago and I don't want to buy a new computer again.

QUESTIONS TO BE ANSWERED:

How is determined how much memory is available in an ST ???
What does the MMU, besides generating Ras,Cas etc. ??
Are there problems to get a VideoBase above 4MB, if there is more than 4MB ??
How would the cheapest hardware solution look like ??

Okay folks, let's get going..

Walter

>Yes the A1200 has a limited 24 bit address bus, just like the Falcon.

The A1200 has a 24-bit adress bus, that means that you can have max.
10MB (2MB Chip+8MB FAst) Ram. The data-bus is full 32 bit.

>: And before you start talking about cripled bus on the F030; do you know
>: ANYTHING about the TIMING and SHARING of the bus in EITHER of the F030
>: and A1200?? I know a bit about the F030, but nothing on th A1200.

The Amiga has 2 types of RAM: Chip and FAst. The custom chips have priority
on the Chip RAm, but the CPU can access to it.

The fast RAM is CPU-only.

this is the main difference: The Atari has only ``Chip-ram'', so the
CPU is always slowed down when the RAM is accessed by other chips.

>>this chip is as I am not very experienced with a soldering iron ...
>
>I would not recommend this - it can be done, when using ESD
>precautions, but there is a much easier way:

I think Christopher's problem is that his shifter is not socketed. Mine wasn't either, neither was the MMU... as I found out when attempting to install a Frontier (now Marpet) Xtra-RAM board.

Frontier promptly supplied a 40-pin socket, which you solder on top of the shifter. You need a low wattage soldering iron (you don't need a lot of heat to make the joints, and there's a lower chance of you frying the chip).

The technique is to fit the socket onto the shifter (the socket legs grip it a little) and apply the iron to the first pin. Simultaneously apply multicored solder to the pin (not the iron) and remove solder and iron as soon as the solder has melted. Repeat for the other 39 pins!

If you are not experienced with a soldering iron, then get some soldering practice on an old PCB / chip / some wires.

For socketed MMUs, Frontier supplied a socket that fits over the top of the MMU. Unfortunately that didn't work for me, as I have an MMU that doesn't support uneven memory banks (the Frontier upgrade was to take my 1040STFM to 2.5MB -- 0.5MB in bank 0 and 2MB in bank 1). I therefore had to cut tracks and make connections on the MMU socket, and clip resistors on the STFM circuit board. Hopefully you won't have to do this (!), and the Frontier Xtra-RAM deluxe board has features to solve the problem in a simpler manner.

>The Falcon does NOT use a shared bus between processor and video!
>How many times does this have to be said???

It will have to be said many, many times since it is not true.
The old ST/E's did not have a shared video/memory bus. The Falcon does.
If you have any evidence to the contrary, please post it. Everything
I have seen and read, however, points to the shared bus situation.

>:[...]
>: I know a little about both. The Falcon has no provision for processor
>: only memory, which the processor can access no matter what the custom

>able to use any amount of virtual memory up to 4 Gb. In my opinion, the
>A1200 is seriously crippled, since it is limited to only 16Mb.

Did nobody ever tell you that it is RUDE TO SHOUT :-) Wrong on a couple
of counts there. A: The A1200 is in fact limited to 10 MB of memory,
not 16. B: Never say never. It is quite easy to add an 030 processor
to the 1200 via the trapdoor expansion slot. This processor will quite
happily be able to access any memory up to the 4Mb limit. Whilst you
may not consider this to be particularly viable, you would do well to
consider how you propose to add 4Gb of memory to your Falcon.
Which bings us neatly to point C: The Falcon has a Surface Mounted 030
on a 24 bit address bus. Or to translate the Falcon has a 14Mb memory
limit (Since 2Mb is reseved by the system). Does this now mean that the
Falcon is even more crippled than you originally supposed that A1200 to
be? Which finally brings us to D: People who need 16Mb's of memory are
unlikely to by either an A1200 or A Falcon 030. That is why there
exists an Amiga 4000 and will exist a Falcon 040.

As for virtual memory does MultiTos support it?

>: Either system without any fast ram will suffer in performance as
>: graphically intensive screen modes are used, as the processor will be

>: able to access memory far less frequently. A system with fast ram
>: however will not suffer.

>Wrong. Since the Falcon has separate buses for CPU and video system
>memory accesses, graphically intensive modes will not even slow the
>Falcon down to half its speed - The A1200 has been said to stand
>STILL at 640x480x256...

I will maintain that you are wrong about the shared bus.
As for slowing the Falcon down to 1/2 it's speed, you already have a 16
bit data bus for that :-)

However, standing still is relative. If you were to go back and read
the discussions about this in c.s.amiga.advocacy, you would find that
the new 640x480x256 was nearly identical in speed to the old amigas
640x480x16. Personally I consider that a great improvement. Coupled
with the improved OS routines some graphic operations were up to 6 times
faster. The overall result is a machine that is far faster.

Oh wait, "said to stand STILL at 640x480x256..."
^^^^
Objection your Honour, Heresay.
Objection Upheld.

We still have no information about the Falcons graphics performance.
Perhaps we should suspend this argument until then.

>: Name any homecomputer at under 1000$ that have CD quality 16bit sound
>: and a processor with a 32 bit data bus?
>:
>: The Falcons sound is it's strength and I can see it doing very well,
>: But there is more to any personal computer than a good sound chip.

>Yes, for example virtual memory, 16 bit/pixel graphics (I won't even call
>it True Colour), GEM, a lot of software (which still runs, as opposed to
>the A1200), D/A and A/D converters (this is NOT part of the sound chip)...
>And last but not least the DSP which is capable of much more than just
>realtime sound effects - for example video phones, software modems with
>integrated FAX, and of course serious number-crunching...

Ok lets start at the beginning

1: Virtual memory - The Falcons OS does not support it, hence it is
left to 3rd party developers. The exists already a 3rd party VM
solution for those Amigas with MMU's, which as I am sure you will be
quick to point out, does not include the A1200. The 4000 in the other
hand...

2: Your 16bit graphics consists of 32768 colours. The true colour mode
is not available in 640x480 VGA modes. The maximum resolution for
the true colour mode is 768x480 interlaced and overscanned.
The A1200 hundred can display 640x480 (+overscan) in 262144 colours.
This is in Ham8, and from a 24bit palette. Alternatively, and more

comparable to the Falcon, it can support 1280x400 interlaced (+overscan). This mode is in theory capable of displaying over 700 000 colours, again from a 24bit palette. This mode, incidentally, has been shown running an amination at 25 frames per second, with the rest of the system still multitaking.

3: Gem and lots of software. :-)

4: A lot of software which still runs? Perhaps you are thinking of the 3 games ST Format managed to get running, after the rest of their games failed. Obviously you _are_ thinking of games, since to my knowledge only one 'serious' application has failed to run on the new Amigas. Even then tests by UK Amiga magazines have shown that about 85% of games released over the last year run quite happily on an A1200. Let he who is without sin cast the first stone?

5: The A/D and D/A. I fail to see what possible difference it could make if these were integrated in to the sound chip. With regard to the sound chip, as far as I have been able to gather, what it lacks in flexibility, it gains in the dsp :-)

6: Software modems - Yes, the DSP could handle that quite happily, but at the same time as compressing/decompressing data in realtime for your video phone and integrated fax? I think you grossly over estimate the abilities of the 56001.

>PS: Will this discussion ever end?

As you can see, no. And I do not believe I even mentioned the Falcons 16 bit data bus. Perhaps it is time to rename this thread?

4525. Re-upgrading an STFM520/1040

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-26 14:29:28 UTC
From: malcolm@logcam.co.uk
Message-ID: <malcolm-261192142529@158.234.41.244>
Source record: 41820

A friend(?) of mine upgraded my STFM520 to 1 meg memory a couple of years ago (using one of those chip-only kit's). Ever since I have had problems (patterns of equally spaced dots appearing on screen after 30 mins or so). Turning the extra half meg off with a bit of software clears this up.

My problem is this:
I'm now going to be using my ST a bit more and so would like to fix this problem properly. If I install one of the 'solderless' upgrades for 0.5 meg to 2 meg will this bypass the faulty upgrade ? Are there any other solutions ? I'm a bit dubious of parcelling up my ST to send to a repair service.

Thanks for your help,

Malcolm.

I did not, but I did not want to be drawn into an argument over what
qualifies as a coprocessor. Too late for that now...

I assume that the original poster was refering to the Amiga's blitter
when he mentioned the "videoshifter". Given that it is capable of
performing 256 logical operations on source data to procuce and output I
believe that the term "coprocessor" is justified. As for the ST's
"videoshifter" it probably does qualify, though few developers seem to
believe it is powerful enough to merit that title.

The video chip in the Amiga also contains a coprocessor called the
copper, which, you may be interested to hear, stands for copprocessor
:-)

As for the sound chip - who knows? Perhaps Commodore just got their
marketing right for once :-)

Walter Ebeling writes that the additional MMU is very expensive. The price of a chip is not so bad compared to the capabilities and the development cost. Memory boards based on this chip work fast and reliable. The people who developed the chip are flexible. If you buy the chip in quantities you can get very good discounts.

Andi

P.S.: If somebody is interested to get in contact with the developers of the Austrian MMU, i can mail him the address.

All 16MB of the valid address space is accessible to all devices,
including video, just like in older STs.
>
>2) How many clocks are memory access to the the display memory.

Dunno. Let's see though, my timings show around a 50% decrease in system throughput between the fastest/cheapest video mode (384x240x4, 15.75khz) and the slowest mode (768x480x65536, 15.75khz, interlaced). These figure at 1.3MB/sec vs 21.1MB/sec, respectively. In order for the video system to consume that much bandwidth and still leave *anything* left over for the CPU, it *must* be operating via a 32 bit data bus, at least. (We know the TT uses 64 bit video access, so it's not out of the question for wider than 32 on the Falcon.) Given that the system throughput is approximately halved, that pretty much nails it at 32 bits.
>
>3) Is there or is there not provision for adding expansion memory
> that is not shared or display memory?

Nope. Adding fast RAM is purely a 3rd-party venture, not something explicitly provided for in the system.
>
>4) If so, how the expansion space partitioned? Is it really up to
> 14 M-byte of display memory or is there some split?

I guess that was answered in (1).
>
>More questions:
>
>4) Is the ROM 16-bits or 24-bits?

Eh? The ROM lives at a 24 bit address, if that's what you mean.
>
>5) Is there any connector for adding a "processor expansion"

> 32-bit data busses?

The 68882 socket, for one.

Right, the so-called processor-direct-slot is A24/D16.
>

Relief? Like what, besides private RAM? If one could make a fast RAM
expansion that only excluded video access (i.e., allowed all other
peripherals to have access) that would be sufficient, eh?
>
>> Yes, for example virtual memory, 16 bit/pixel graphics (I won't even call

>
>1) What resolutions are supported by the 16 bit/pixel graphics?

On the broadcast-video displays (TV and old Atari-RGB) all resolutions
are supported, with interlace and overscan available.
>
>2) Is it true that the 16-bit/pixel mode slows down the Falcon to a crawl?

Not quite crawling, more like walking instead of running, tho. }-)
>
>And the ability to change resolution and video mode in mid-screen

Sounds nice, but the ST line doesn't have "text" modes in the first
place, so ... Ah, for a display-list based graphics system...
>
>With respect to your other points:

>
>1) Has Atari made any noises about supporting VM in Multi-TOS? It's
> kind of pointless to boast a feature for which there is no

Not certain. I guess memory-protection is half the battle, and that's
already in place. Since Atari isn't currently pushing their Unix port,
I'd expect them to add that kind of Unix functionality to MultiTOS. We've
had abit of discussion about this in MiNT but nothing yet.
>

Well, Atari is creating a lot of incentive for developers to try to
realize that potential. I think it'll show...
>

Sounds nice. I wanted to play with the one at the Motorola booth at
Comdex but didn't really have a chance, was too short on time.

For the curious, here's a relatively complete table of timings showing
video modes' impact on Falcon performance.

ARC file extract times for various Falcon graphics modes...

Display Frequency Rez Colors Time in Difference from

Mono 35khz 640x480x2 6140 3.6%

Mega, Turbo-16, 640x200x4 10129 70.9%

These are the times to extract the contents of a 350K ARC file using a RAMdisk for all file operations. The times are given in clock ticks, (5ms per tick on all Ataris) with a percentage factor showing the ratio of a given time compared to the best time. I also show the timing for my Mega ST with Turbo-16 accelerator (16MHz 68000 w/32k cache) for comparison.

Whoever said the Falcon video and CPU didn't share bus access is definitely mistaken. While these timings don't reflect pure CPU/Memory performance, (the output from ARC caused text to be scrolled across the screen, after all, which adds scrolling overhead into the figures) it does reflect a pretty realistic use of the system (some computation plus some screen activity).

As for true color graphics bringing the system to a complete stop - well, that's obviously an exaggeration, but not too far from the truth. The CPU is obviously getting only half as much bandwidth as it got compared to the "cheapest" video modes.

Finally, it appears that the 16 MHz 68030 Falcon is around 60% faster than the 16 MHz 68000 in my Mega ST, which in turn is about 40% faster than a stock ST. That would seem to imply that the total performance is just around twice that of an 8 MHz 68000, which can only mean the CPU has 16 bit access toe system RAM, and the difference in clock speed accounts for the observed performance. (Of course, I could be pretty far off base here; the Falcon's TOS is much different from the TOS 1.4 in my Mega, etc...)

Not sure about that, but probably true. Never wise to buy a system in an
already-maxed-out configuration, eh? Still, I can see a lot of folks
buying 'em and getting 3rd party expansions in the future.
>
>As for virtual memory does MultiTos support it?

Nope. Existing docs don't mention it either, I guess it's not planned
for the initial release, anyway.
>

There is also at least one existing 3rd party 68030 VM system for Atari,
from Fast Technologies.
>
>2: Your 16bit graphics consists of 32768 colours. The true colour mode

65536 colors, but who's counting. (*We* are! }-)

> estimate the abilities of the 56001.

Uh, if you have only one phone line, you only need to do one of those
at a time - data modem, fax modem, or videophone, eh? All easily within
the realm of possibility. And since the Falcon030 is aimed at the home/
consumer market, multi-line phone service isn't really an issue. (Nor is
it completely ruled out, either...)

>>PS: Will this discussion ever end?

Hans Holmberg (hasse@solace.hsh.se) wrote:
:
: Well, what you need is a hostadaptor. It converts the SCSI to ACSI, wich is not
: compatible. (god knows why Atari made it so)

You don't have to be God to explain why they implemented ACSI :)
If you look at the ACSI interface, it is nothing more than a
slightly souped-up external 8-bit DMA interface which is both
very easy to implement in hardware _and_ offers a relatively cheap
way to "upgrade" to SCSI using a host adaptor. In some respects,
ACSI even has a slight edge over pure SCSI: The command overhead
is very low, and it is quite easy to program an ACSI transfer.
ACSI just suffered from some flaws: The hardware interface was
not very stable (no buffering etc.) and the DMA chip cannot handle
transfer speeds exceeding ~1.5 MB/s and transfer sizes > 255*512
bytes. Remember that at the time of ACSI's design, most affordable
hard drives were small (~20 MB) and slow (~500 KB/s).

It seems quite strange that Commodore officials find it necessary to
ask questions in comp.sys.atari.st about the Falcon design...

grr@cbmvax.commodore.com (George Robbins) writes:
: In article <1992Nov25.143111.10352@email.tuwien.ac.at> nino@vmars.tuwien.ac.at (Marinos Yannikos) writes:
: > [...]
: > The Falcon does NOT use a shared bus between processor and video!
: > How many times does this have to be said???
:
: Please elucidate!
:
: [...]
: So, unless there is some very efficient access to the display RAM for
: the video subsystem, there will be contention between the processor and
: the display accesses. If there is a separate bus for RAM expansion and
: other processor activities then is possible to attain higher performance.
:
: So far, I've several different stories about the Falcon video bus and
: display subsystem, most of which are probably confusion. On one hand,
: people are asserting that there isn't a shared bus and on the other,
: they are asserting that all 14M-byte of RAM on the Falcon can be used
: for dipslay memory. Unless there is some kind of configurable bank
: switching, this seems to offer a contradiction. It may be that the
: processor and diplay busses are separate, but leave the question open
: as to whether you have also have expansion memory that isn't subject
: to display access contention.
:
: If you can answer the following questions:
:
: 1) What is the basis for sharing display memory between the processor
: and the display subsytem.

Have a look at the previous posting by hasse@...

:
: 2) How many clocks are memory access to the the display memory.

I have no idea. But they are full 32 bit accesses, so this depends on
the RAM speed I'd say...

: 3) Is there or is there not provision for adding expansion memory
: that is not shared or display memory?

As in the TT, fast RAM may not be accessed by the video-shifter...

: 4) If so, how the expansion space partitioned? Is it really up to
: 14 M-byte of display memory or is there some split?

Yes, the shifter can access 24 bit (the upper 2 mb are used by the ROM
and hardware registers) so there can be 14MB of video memory.

What about the A1200? Can you answer the same questions?

: > [...]
: > An 68EC020 however can only address a MAXIMUM of 16 Mb RAM, it can NOT
: > provide virtual memory (like the 68030 with built-in PMMU) so you will
: > _never_ be able to use more than 16Mb of memory! The Falcon will be
: > able to use any amount of virtual memory up to 4 Gb. In my opinion, the
: > A1200 is seriously crippled, since it is limited to only 16Mb.
:
: You may be missing the point that the A1200 expansion connector has full
: access to the system internals and it is a trivial excercise to implement
: an expansion board that includes a 68030. It is not much harder to do

So why didn't commodore use a 68030 right away? To make it a bit cheaper
and sell more expansion boards later, eh?

: one which would incorporate a >> 14/16 MHz processor. Such a board would
: probably also include fast memory tightly coupled to the processor which
: would provide much higher performance than the base unit.

So all you need to get what the F030 already has, is an expansion board
with 68030/PMMU, new memory and some other "minor" changes to make the
whole system run at 16MHz. Right? Now add the cost of such a board to
the price of the A1200, and compare with the F030. (And you don't even get
a DSP and falcon sound-system)

: As a result, the 16M-byte limitation and lack of VM support you cite
: are not architectural limitations, the are simply features that, while
: not included in the base unit, can be added via expansion provisions.

And extra cost, eh?

: More questions:
:
: [..]

better ask some hardware-guru... :)

: I would point out that the Atari COMDEX spec sheet makes no mention at
: all of a "memory expansion" connector, only an expansion port said to
: support x86 compatibility boards. According to postings here, this
: connector seems to say that it is only 24-bit addresss, 16-bit data.

Well, on the other hand, I don't think commodore mentioned the additional
cost to get more than 2Mb video ram into the A1200 - or more than 16Mb
RAM total for that matter! :)

: [...]

: Non-interlaced, 640*480*256 will slow down the A1200 considerably -

How much is considerably? :) 90% perhaps?

: interlaced or with some intermediate number of bit-planes, far less so.

And how much is "far less so"?

: With the addition of some fast memory expansion, there would be little
: overall processor slow-down, though there would still be contention
: when accessing display memory.

Well, I think what people are interested in most is what they get
with the A1200, without having to spend a lot of money for expansions.

: 1) How much does 640*480*256 non-interlaced slow down the Falcon?

That information was posted a while ago (by Howard Chu I think).

: 2) Is there any relief available for the "graphically intense"
: modes that make the Falcon "stand STILL"?

I don't think there are any such modes for the Falcon! :)

: Another factor not really mentioned is how much access to display
: memory is required to animate the display of typical games. The
: 8 64-bit sprites in the A1200 and their hardware prioritization
: with one 256-color or two 16-color "playfields" can implement many
: game displays with less byte-bashing than the Falcon "dumb frame
: buffer" video subsystem.

Wow! The perfect game console, eh? And btw, the Falcon does have a
fast blitter.

: > : Name any homecomputer at under 1000$ that have CD quality 16bit sound
: > : and a processor with a 32 bit data bus?
: > :
: > : The Falcons sound is it's strength and I can see it doing very well,
: > : But there is more to any personal computer than a good sound chip.
:
: I would point out here that the A1200 has two possible expansion
: points for adding DSP/16-bit sound. One is the industry-standard
: PCMCIA port, which lends itself to DSP's which use the SRAM buffer
: model used by the Falcon. It is also possible to add a DSP via
: the processor expansion slot, which would provide full/width high
: bandwidth access to the DSP subsystem, which could also be a bus
: master.

Oh, it's expansion time again... How about OS support for that DSP?
Anything that developers can RELY on that it is available? Most
developers are probably only interested in writing programs for
ther broadest market possible, so you can't expect them to support
such 3rd party DSP boards (if they'll ever exist).

: > Yes, for example virtual memory, 16 bit/pixel graphics (I won't even call
: > it True Colour)
:

: 1) What resolutions are supported by the 16 bit/pixel graphics?

Up to 768x576 as far as I know (haven't tried it myself)

: 2) Is it true that the 16-bit/pixel mode slows down the Falcon to a crawl?

No, as I said, look at the information posted some time back by H.Chu.

: Though the HAM-8 mode isn't "true-color", the 1280*480 HAM-8 interlaced
: display mode effectively provides a 420*480 image with 18 bits of
: arbitrary color per-pixel, and gets better where gradual shading of
: real-world images allows the base-register/color-increment nature of
: HAM to come into play.

Oh yeah? What about the restrictions of all HAM modes? How much processor
time do they leave for the programs? What about a genlocking bit?
HAM=Hold And Modify... Haha...

: While 16-bit "true-color" is a step beyond the 256 color modes, it
: will be interesting to see how A1200 HAM-8 images compare to the
: Falcon images.

Yes, and it would be interesting to see how useable these modes are.
The 16bit mode on the Falcon has NO restrictions whatsoever, what
about the A1200 HAM modes?

: [...]

: With respect to your other points:
:
: 1) Has Atari made any noises about supporting VM in Multi-TOS? It's
: kind of pointless to boast a feature for which there is no
: system/software support.

Does Atari have to make noises about it? What about memory protection
in the A1200?

: 2) GEM...

Yes? What about it?

: 3) "Most Software" runs on the A1200. The software that doesn't is
: exactly the same class of stuff that will either die on the
: Falcon or take no advantage of the new capabilities of the
: system - namely the cheap Game software that ignores the OS
: and manipulates the hardware directly.

Oh yes... this means about 90% of all Amiga games for example...

: 4) DSP - all of the things you mention are possibilities, but so far
: DSP's seem to serve mostly as audio-output engines and the
: rest is all either un-realized potential or things that work
: better when you buy a "black box" and plug it in.

Well, the DSP is already being used by several companies for other things
than audio-output - eg. phong shading in a game.

: > PS: Will this discussion ever end?
:
: I could aplogize for getting technical, but I have a certain degree
: of knowledge about the A1200 internals. Some of the questions raised
: above are sincere requests for information, since I have no access
: to a Falcon or the developer documentation, others are intended more
: to prick at some of the assertions or contradictory claims made by
: Falcon adherents.

Fine. If you find it necessary to post to comp.sys.atari.st to
flame back (at least that's what it looks like) no problem!
So much about the Commodore officials being more diplomatic...
(someone claimed that in an earlier posting)

: A while back, I might have admitted that the Falcon would give the
: A1200 (as it comes out of the box) some competition performance-wise,
: but the 16-bit memory makes me wonder. I can state that the A1200
: expansion provisions allow it to transcend the somewhat limited
: capabilities included, but it isn't clear if this is also true of
: the Falcon.

There is no 16-bit memory... *sigh*
"somewhat limited", eh? I wonder why commodore designs such systems,
just to claim they'd be better than the falcon if you added a bunch
of expansions...

: The Falcon does have some nice features built-in, notably the SCSI
: port, the 16-bit sound/DSP system, and (maybe) the LocalTalk port,

SCSI-2 port.

: but I think that these capbilities can all be added via the A1200
: expansion provisions if the user needs them, and in some cases
: the add-on expansion will provide better solutions - a PCMCIA
: Etherent adapter would be more useful (for me) than an Apple'ish
: LocalTalk port.

For you. Fine. For me a SCSI-2 port is more useful than IDE, and
a DSP and falcon sound subsystem is more useful than the poor A1200
sound system, and the Falcon's 14Mb RAM accessible by both video
system and CPU are nice too.

: It should also stand for something that the A1200 has a big-brother,
: already shippping, the A4000. This *68040* system is available
: today, and while highly compatible with the A1200 and other Amiga's

Haha! If it's "highly compatible" with the A1200, I wonder how
compatible it is with the A500...

: offers a multi-slot expansion bus, 2 M-bytes of display memory and

2 Mb? Isn't that great.

: up to 16 M-bytes of fast memory (SIMMS) on the motherboard, with
: available memory cards providing at least 64 M-bytes memory per card.

And the poor old Amiga soundchip I think? Hmmm... I saw one A4000 at the PC-Expo here in Vienna... Not many other people did... :) Some rather simple demo was running, didn't really impress me...

: nino@vmars.tuwien.ac.at (Marinos Yannikos) writes:
: [stuff deleted]
: >The Falcon does NOT use a shared bus between processor and video!
: >How many times does this have to be said???
:
: It will have to be said many, many times since it is not true.
: The old ST/E's did not have a shared video/memory bus. The Falcon does.
: If you have any evidence to the contrary, please post it. Everything
: I have seen and read, however, points to the shared bus situation.

Well... depends on what you mean by "shared video/memory bus".
If you look at the posting by hasse@... you can see, that both
the CPU and video system access memory through the COMBEL.
There is a 16 bit bus from the COMBEL<->CPU and a 32bit bus
to the video system. So there are separate buses for CPU and
video memory accesses until the COMBEL, then of course the
same 32 bit bus is used.

: [...]
: >An 68EC020 however can only address a MAXIMUM of 16 Mb RAM, it can NOT
: >provide virtual memory (like the 68030 with built-in PMMU) so you will
: >_never_ be able to use more than 16Mb of memory! The Falcon will be
: >able to use any amount of virtual memory up to 4 Gb. In my opinion, the
: >A1200 is seriously crippled, since it is limited to only 16Mb.
:
: Did nobody ever tell you that it is RUDE TO SHOUT :-) Wrong on a couple
: of counts there. A: The A1200 is in fact limited to 10 MB of memory,
: not 16. B: Never say never. It is quite easy to add an 030 processor

SORRY FOR SHOUTING! If you enforce my statement, fine with me! :)

: to the 1200 via the trapdoor expansion slot. This processor will quite
: happily be able to access any memory up to the 4Mb limit. Whilst you
: may not consider this to be particularly viable, you would do well to
: consider how you propose to add 4Gb of memory to your Falcon.

Well... You'll have to pay a lot of money for a 68030 (OS support?)
I'm talking about built-in features, not expansions. Who knows what
expansions will be available in 2 years for either of the 2 machines?
There is even a 68040/66 expansion for the good old ST around now...

: Which bings us neatly to point C: The Falcon has a Surface Mounted 030
: on a 24 bit address bus. Or to translate the Falcon has a 14Mb memory
: limit (Since 2Mb is reseved by the system). Does this now mean that the

What about virtual memory on the falcon? quite easy to add, with NO
additional cost (except for software).

: Falcon is even more crippled than you originally supposed that A1200 to
: be? Which finally brings us to D: People who need 16Mb's of memory are
: unlikely to by either an A1200 or A Falcon 030. That is why there
: exists an Amiga 4000 and will exist a Falcon 040.

I don't need more than 16Mb, but 14Mb are still very useful. Especially
with multi-tasking. A lot better than 8Mb haha... (and 2 MB video ram...)

: As for virtual memory does MultiTos support it?

I'm no developer, so don't ask me.

: [...]
: I will maintain that you are wrong about the shared bus.

I will not.

: As for slowing the Falcon down to 1/2 it's speed, you already have a 16
: bit data bus for that :-)

Simple calculations for simple minds, eh? There is not much slow-down
from that 16 bit bus, since video ram is accessed much more frequently
the sharing of memory accesses (note: not of one bus) is much more
"fair" in the falcon. BTW, you can slow down the A1200 to more than
1/2 easily! :) Just switch to 640x480x256! It's no point in comparing
the Falcon and A1200 speeds, we both know the Falcon is faster in
ALL modes. Just try it...

: However, standing still is relative. If you were to go back and read
: the discussions about this in c.s.amiga.advocacy, you would find that

Sorry, I don't read that mindless bashing group... I already feel
guilty for answering all these postings in c.s.a.st ...

: the new 640x480x256 was nearly identical in speed to the old amigas
: 640x480x16. Personally I consider that a great improvement. Coupled
: with the improved OS routines some graphic operations were up to 6 times
: faster. The overall result is a machine that is far faster.

FAR faster... :) How about some real world tests, not theory?

: Oh wait, "said to stand STILL at 640x480x256..."
: ^^^^
: Objection your Honour, Heresay.
: Objection Upheld.
:
: We still have no information about the Falcons graphics performance.
: Perhaps we should suspend this argument until then.

We have... *sigh* (3rd time) Howard Chu posted information about this
(speed relative to the 8MHz ST) a few days ago...

: [..]
: Ok lets start at the beginning

OK. (Do I have to answer everything twice?)

: 1: Virtual memory - The Falcons OS does not support it, hence it is
: left to 3rd party developers. The exists already a 3rd party VM
: solution for those Amigas with MMU's, which as I am sure you will be
: quick to point out, does not include the A1200. The 4000 in the other
: hand...

How do you know the Falcon's OS doesn't support it? Have you seen it?
Do you have a falcon? And why do you always refer to the A4000 when
you find out the A1200 is lacking something the Falcon has? So you admit
the A1200 is no match for the Falcon? (030)
BTW, there are enough 3rd party VM solutions for the TT already.
(I don't know about the Falcon, but I guess there are too)

: 2: Your 16bit graphics consists of 32768 colours. The true colour mode

65536 or 32768 with 1 overlay bit.

: is not available in 640x480 VGA modes. The maximum resolution for

It is in 768x576 PAL mode.

: The A1200 hundred can display 640x480 (+overscan) in 262144 colours.
: This is in Ham8, and from a 24bit palette. Alternatively, and more
: comparable to the Falcon, it can support 1280x400 interlaced
: (+overscan). This mode is in theory capable of displaying over
: 700 000 colours, again from a 24bit palette. This mode,
: incidentally, has been shown running an amination at 25 frames per
: second, with the rest of the system still multitaking.

At what speed? With what HAM restrictions?

: 3: Gem and lots of software. :-)

Why do you Amiga owners all complain about GEM? It's a very powerful
Environment - just have a look at some commercial programs which make
use of most of its features!

: 4: A lot of software which still runs? Perhaps you are thinking of the
: 3 games ST Format managed to get running, after the rest of their
: games failed. Obviously you _are_ thinking of games, since to my
: knowledge only one 'serious' application has failed to run on the

Yes, and by 'serious' you probably mean applications which you were hoping
they'd run...

: new Amigas. Even then tests by UK Amiga magazines have shown that
: about 85% of games released over the last year run quite happily on
: an A1200. Let he who is without sin cast the first stone?

Huh... I wonder how hard it was to find these games so they could test them...

: 5: The A/D and D/A. I fail to see what possible difference it could
: make if these were integrated in to the sound chip. With regard to
: the sound chip, as far as I have been able to gather, what it lacks
: in flexibility, it gains in the dsp :-)

Have a look at the sound subsystem specs for the Falcon and answer
that yourself. It's far more flexible than the naive sounchip/DMA sound
combination.

: 6: Software modems - Yes, the DSP could handle that quite happily,
: but at the same time as compressing/decompressing data in realtime
: for your video phone and integrated fax? I think you grossly over
: estimate the abilities of the 56001.

Am I? So why were those applications demonstrated at the Comdex then?
I wasn't there, so I apologize if I was wrong. I read in an earlier
posting about that.

: >PS: Will this discussion ever end?
:
: As you can see, no. And I do not believe I even mentioned the Falcons
: 16 bit data bus. Perhaps it is time to rename this thread?

Or take it to comp.sys.amiga.advocacy or what it's called...
I'm SOOOO bored.

From: cstadbs@csv.warwick.ac.uk
Message-ID: <1f3dl6lNNjjd@clover.csv.warwick.ac.uk>
Source record: 41835

A few days ago I read in a UK ST mag that the DSP was capable of very
fast maths calculations such as vector, scalar and matrix calculations. These
functions seem to be ideal for 3D graphics applications(including phong
shading and ray tracing) and games.
I have had a quick look at the FAQ for comp.dsp and it seems that all
of the above is true. Can anyone give more details and answer the following
questions:-

1) Will the DSP have to be programmed separately or can the above functions
be controlled by the 68030?
2) What languages/compilers support the DSP so far?
3) Can anyone give a list of current DSP projects (including graphics
and games?

Thanks,

Paul

>Is the latest version of GCC ported to the Atari version 2.2.2 ?
>Also, what is the latest version of MiNTlib (and is it compatible with
>whatever the latest version of GCC is)?

Finally an easy question to answer... The latest version is 2.3.1, you
can find it in Gnustuff/Tos/Gcc on atari.archive. The latest version of
MiNTlib is patchlevel 24, and you can find a copy of GCC 2.3.1 linked with
that in Mint/Gcc on atari.archive as well. The MiNT version is much the
same as the TOS version but has been compiled with PC-relative and base-
relative code, making it a little more compact, slightly faster, and
sharable under MiNT 0.96. (Thanks to Thomas Schulze for packaging it up.)
Both versions will run fine under both MiNT and TOS, the MiNTlib version
handles signal trapping differently, (uses MiNT facilities, obviously)
and so on.

That's pretty good, better than the un-expanded A1200.

> >3) Is there or is there not provision for adding expansion memory
> > that is not shared or display memory?
>
> Nope. Adding fast RAM is purely a 3rd-party venture, not something
> explicitly provided for in the system.

OK.

> >4) Is the ROM 16-bits or 24-bits?
>
> Eh? The ROM lives at a 24 bit address, if that's what you mean.

Oops, I though I had corrected that before it went out. The ROM in the A1200 is 32-bit/3-clock/no video contention to speed up the system routines in ROM. Unless otherwise stated, I would guess that the Falcon ROM isn't subject to video contention, but is probably only 16-bit.

> >5) Is there any connector for adding a "processor expansion"

> place, so ... Ah, for a display-list based graphics system...

Well the Amiga doesn't have "text" mode either, but a screen that is
used primarily for text can use only maybe 1-3 bitplanes, where one
used for image display might use 8 or the HAM modes.

Is the "true-color" display mode fully supported by the system graphics/
text rendering/windowing routines in some seamless manner or is it
support as a special "full screen" image display mode?

> >2) GEM...

Well, have you checked, that the parity of the drive is disabled ?
I have the AdSCSI Micro Adapter for the Mega ST and it will not work
with the drive's parity enabled, as I have found out when I connected a
60Mb Conner hard disk, which has no option to change the parity.
When I booted the driver, I got 'Cannot find adapter' and 'Clock not
present'. Hence there was no icon, and the formater would not find any
SCSI device and hence quit.

So, make sure that you disbale the parity, if you can't, bad luck, you
will need a different disk mechanism. If you already have, I have no
idea what causes your problem.

In the hope that you forgot the parity and can change it:

Good Luck
Michael

Why? I can't buy one anywhere and attempting to obtain pre-release devloper documents or similar data would be a bit under-handed, wouldn't it?

I do have access to the facts regarding the A1200, and if I want to peer through all the rumors to find out what this Falcon thing is then asking questions seems like a reasonable approach.

If you would read some of the "Falcon" postings that have showed in comp.sys.amiga.* you might see what an inaccurate or incomplete description of the machine the Atari *and* Amiga fans have been posting there.

By the way, please note that I am not a "Commodore Official", but rather a mere engineer involved in the A1200 project...

There seems to be a question about whether "TT" style Fast Ram is
supported or not. Do you have a clear answer on this? Does the memory
expansion connector provide 32-bit address/32-bit data expansion
beyond the 24-bit address limit, or does it only support added display
memory on the shared memory bus?

> : 4) If so, how the expansion space partitioned? Is it really up to
> : 14 M-byte of display memory or is there some split?
>
> Yes, the shifter can access 24 bit (the upper 2 mb are used by the ROM
> and hardware registers) so there can be 14MB of video memory.
>
> What about the A1200? Can you answer the same questions?

Sure, 2 M-byte dedicated display memory, up to 8 M-byte "fast memory"
with the internal 68EC020, ~4 G-byte with a processor/memory expansion
card.

Whether 2 M-byte of video memory is "enough" is certainly a subject
subject to discussion, as there are certainly lots of neat things
you can do by filling 14 M-bytes (if you have it) of video memory
with image data and flipping around between them. Whether this goes
beyond the ability to create cool animiated video loops for "killer
demos" is another question.

> : > An 68EC020 however can only address a MAXIMUM of 16 Mb RAM, it can NOT

> and sell more expansion boards later, eh?

No, more because our analysis showed that the 68030 wouldn't improve
performance enough to justify the additional cost. Other design options
such as providing a 32-bit processor<->memory bus, 32-bit wide ROM, the
PCMCIA port and a full-access processor expansion port did seem to
justify their cost.

The Falcon has some new "features" built in that were not present on
previous Atari systems, but still lacks some that are present in

every Amiga system. We could argue for a year or so about which are
signicant, but in the end, only the marketplace will tell whether either
Atari or Commmodore hit the right mix of features and retail price.

> a DSP and falcon sound-system)

Not exactly, what I would claim is that we already have the essentials
and the expansion provisions allows those users that want to extend their
systems a "clean" way of doing so. Such expansion can go far beyond the
built-in features of the A1200 (or the Falcon) if that's what the user
wants and is willing to pay for.

You're confusing cost with having extensibility at all...
...

> Well, I think what people are interested in most is what they get
> with the A1200, without having to spend a lot of money for expansions.

Of course, but if the user finds that that two are equivalent for
his intended use, he will certainly look at the expansion possiblities.

> : 1) How much does 640*480*256 non-interlaced slow down the Falcon?

You might want to review Howards observations. Admittedly "stand STILL"
might be a bit of an exaggeration, but I was merely echoing the original
posters wording.

>
> Wow! The perfect game console, eh? And btw, the Falcon does have a
> fast blitter.

Games are one of the things it can do well. There seems to be considerable dispute as to whether the Falcon blitter is "fast" or not. Rumor has it that at best it is twice as fast as the "ST" blitter, which was not as fast as the Amiga blitter, nor capable of performing the same operations without multiple passes over the data.

> ther broadest market possible, so you can't expect them to support
> such 3rd party DSP boards (if they'll ever exist).

What I would say here is that every Amiga has had "good quality" sound built in. The 16-bit sound on the Falcon sounds like it is better than what we build in, but it is unique to the Falcon and only "Falcon specific" software will be able to take advantage of it. This sounds like a different version of the same problem to me.

Experience has shown that when there is a good quality expansion product avilable, be it a video card or sound card, the key players for that kind of application will support it.

> : Though the HAM-8 mode isn't "true-color", the 1280*480 HAM-8 interlaced

> : HAM to come into play.
>
> Oh yeah? What about the restrictions of all HAM modes? How much processor
> time do they leave for the programs? What about a genlocking bit?

> HAM=Hold And Modify... Haha...

Please note that the effective resolution I picked was the case where there are no "HAM restrictions", which is to say that it is the worst case where it takes "3-pixels" to effect a complete color change - take the best case 1280 pixels (a bit more with overscan) divide by 3 and you get 420.

Where you do want to take advantage of pixel-to-pixel correlations (your "HAM restrictions") you will much higher apprarent resolution and those are 18-bit (or better) colors, not 16-bit.

As far as Genlock goes, you can do it in HAM, though you "waste" some of the 64 base colors (24-bit)... If you need a technical description ask over in comp.sys.amiga.hardware.

> : While 16-bit "true-color" is a step beyond the 256 color modes, it
> : will be interesting to see how A1200 HAM-8 images compare to the

>
> Yes, and it would be interesting to see how useable these modes are.
> The 16bit mode on the Falcon has NO restrictions whatsoever, what
> about the A1200 HAM modes?

Since the HAM-8 mode is an extension of the existing HAM-6 mode, Amiga rendering packages and paint programs already understand the HAM concepts and need only be extended to take advantage of the extended capabilities.

The utility of any of the true-color modes be they 16-bit, 24-bit or HAM for anything beyond image display is open to question...

> : 1) Has Atari made any noises about supporting VM in Multi-TOS? It's

Well the spec boast the presence of the 68030 PMMU and if the Atari software does make effective use of it, I stand corrected.

>
> There is no 16-bit memory... *sigh*

Sorry, just a 16-bit processor bus interface to a shared 32-bit
memory bus. Right or wrong? Any mitigating factors?

> : It should also stand for something that the A1200 has a big-brother,
> : already shippping, the A4000. This *68040* system is available
> : today, and while highly compatible with the A1200 and other Amiga's
>
> Haha! If it's "highly compatible" with the A1200, I wonder how
> compatible it is with the A500...

The same version of the Amiga chipset is used in the A1200 and A4000,
which makes it "highly compatible". This chipset is a superset those
used in previous Amiga systems, so they are "highly compatible" too.
How compatible is the Falcon with the existing software base? How
compatible would a Falcon040 be?

> : offers a multi-slot expansion bus, 2 M-bytes of display memory and
>
> 2 Mb? Isn't that great.

Great? Sufficient, if you consider that there's also 4 M-bytes of
Fast RAM included and provision for (much) more.

Enough for now...

Have you changed the switch inside the TT that tells TOS that you have
installed a HD-drive? I can't remember wich it was, but isn't it set
the TOS wont recognize the HD-format.

It is 16 bit (on 2 8-bit ROMs, anyway, leaves little room for doubt there).
Dunno about video access. I guess a quick test would be to set the screen
pointer up into the high 2MB region and see what appears on the display.
I may give that a try this weekend.
>
>Well the Amiga doesn't have "text" mode either, but a screen that is
>used primarily for text can use only maybe 1-3 bitplanes, where one

I see. Hm, if you can change modes at an arbitrary X position as well
you can use that for windows as well, eh? That would really be nice. Kind
of like the graphics board I've been dreaming up.
>
>Is the "true-color" display mode fully supported by the system graphics/
>text rendering/windowing routines in some seamless manner or is it
>support as a special "full screen" image display mode?

Yep, fully supported by the VDI; programs that use VDI calls will run without
modification. Programs that write to screen memory directly, assuming old
ST video layout will look very odd. (Too bad, my fractal program falls
into that class. It's certainly an interesting-looking screen, but it's
not a 64K color mandelbrot. It looks more like an edge-tracing of a vaguely
mandelbrot-like object.... }-) The 1, 2, 4, and 8 bit-per-pixel modes use
the same interleaving scheme that the old ST modes used though, so if a
program queries the screen dimensions in those modes (X/Y rez, # planes)
and acts accordingly, it can still write directly to the screen without
trouble.

>Sounds like perfomance issues will really need to be determined by benchmarks,
>which will no doubt entail endless controversy... 8-)

(That conclusion was based solely on the video timing stuff, btw.) Gee, endless controversy in a usenet newsgroup? Who'd ever heard of such a thing...

(ps ps: going back to a distant thread - I thought the 6502 only had 8 address lines and multiplexed to get 16 address bits. Now, as someone said elsewhere, "far be it from me to get into an argument with a Commodore engineer," particularly about something like the 6502, but ... }-)

4546. MiNT: Problems with Psignal, Pfork

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-27 09:18:01 UTC
From: kinzel@ibr.cs.tu-bs.de
Message-ID: <1992Nov27.091801.9394@ibr.cs.tu-bs.de>
Source record: 41748

Hello!

I've got problems with MiNT functions Pfork() and Psignal() (MiNT
version 0.95, PL 13)

- Pfork(): After splitting a process with Pfork() the child starts to
run, but the father falls asleep, why?

- Psignal(): I used the Psignal() call to install a Talarm routine. It
looks something like this:

```
func()
{
/* code */
Psigreturn()
}

Psignal(14,(*func)())
```

The problem is that Psignal causes the defined signal (here 14), and
doesn't install the signal handler (when the prcocess receives the
signal later, the default function (terminated) is executed.

Is there anyone who has an answer?

Thanx Jens

: > (someone claimed that in an earlier posting)
:
: If you think this was more of an intent to "flame back" than an
: attempt to gather information and pose questions which might throw
: more light on the relative merits of the two machines, then I
: apologize.

OK, if it wasn't I apologise, but I'd still like this discussion to
end, please! :-) At least let's not continue it in comp.sys.atari.st.tech!

: > : A while back, I might have admitted that the Falcon would give the
: > : A1200 (as it comes out of the box) some competition performance-wise,
: > : but the 16-bit memory makes me wonder. I can state that the A1200
: > : expansion provisions allow it to transcend the somewhat limited
: > : capabilities included, but it isn't clear if this is also true of
: > : the Falcon.
: >
: > There is no 16-bit memory... *sigh*
:
: Sorry, just a 16-bit processor bus interface to a shared 32-bit
: memory bus. Right or wrong? Any mitigating factors?

Right. Memory is 32 bit wide though.

: > : It should also stand for something that the A1200 has a big-brother,
: > : already shippping, the A4000. This *68040* system is available
: > : today, and while highly compatible with the A1200 and other Amiga's
: >
: > Haha! If it's "highly compatible" with the A1200, I wonder how
: > compatible it is with the A500...
:
: The same version of the Amiga chipset is used in the A1200 and A4000,
: which makes it "highly compatible". This chipset is a superset those
: used in previous Amiga systems, so they are "highly compatible" too.
: How compatible is the Falcon with the existing software base? How
: compatible would a Falcon040 be?

I'd say at least as compatible as a A4000... Did I hear something about
the A1200 crashing when the copperlist is modified? (just asking)

: > : offers a multi-slot expansion bus, 2 M-bytes of display memory and
: >
: > 2 Mb? Isn't that great.
:
: Great? Sufficient, if you consider that there's also 4 M-bytes of
: Fast RAM included and provision for (much) more.

Much more... 4Mb isn't very much... Unless you mean by "provided" that
one can always buy a 68030 card with fast ram...

: Enough for now...

right..

4550. HELP connecting 2 atari-st using aux (retry)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-27 10:42:17 UTC
From: gip405@sci.kun.nl
Message-ID: <ByDF2H.2CL@sci.kun.nl>
Source record: 41755

I want to use my harddisks on both my Atari-st. Therefore I have the programm mx2net (using the midiport). An equivalent version of mx2net is mx2neta for using the modemport.

The problem is: I don't know how to solder a modem-cable.

I already tried to make a modem-cable by soldering a wire to the 1 of connector A to the 1 of connector B, 2 of A to the 2 of B, etc. but this doesn't work.

Can anyone tell me how to solder the wires at the 2 female connectors, so communication between my computers will be possible?

Thanks,

Gijsbert Bronts.

What a wonderful statement. Does that mean I can get a Falcon for free
(with no additional cost except for hardware, of course)?

>: Falcon is even more crippled than you originally supposed that A1200 to
>: be? Which finally brings us to D: People who need 16Mb's of memory are
>: unlikely to by either an A1200 or A Falcon 030. That is why there
>: exists an Amiga 4000 and will exist a Falcon 040.

>I don't need more than 16Mb, but 14Mb are still very useful. Especially
>with multi-tasking. A lot better than 8Mb haha... (and 2 MB video ram...)

Strange, you posted a message saying that the A1200 was "serious
crippled" because it could "only" access 16Mb.

>: As for virtual memory does MultiTos support it?

>I'm no developer, so don't ask me.

Neither I am, but from most reports on the net and in magazines, it
doesn't.

>Simple calculations for simple minds, eh? There is not much slow-down
>from that 16 bit bus, since video ram is accessed much more frequently
>the sharing of memory accesses (note: not of one bus) is much more
>"fair" in the falcon. BTW, you can slow down the A1200 to more than
>1/2 easily! :) Just switch to 640x480x256! It's no point in comparing
>the Falcon and A1200 speeds, we both know the Falcon is faster in
>ALL modes. Just try it...

Not much being how much?
And with regards to the speed of the A1200, adding any extra memory will
enable the processor to run without contention. As compared to the 60%
speed reduction using the true colour modes in the Falcon (from Howard
Chu's posting).

>: However, standing still is relative. If you were to go back and read
>: the discussions about this in c.s.amiga.advocacy, you would find that

4554. Printing from GFA-DRAFT

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-27 11:35:56 UTC
From: "Gerry O'Rourke"
Message-ID: <1992Nov27.113556.28749@nt.com>
Source record: 41752

Hi All!
I am trying to produce some simple drawings using the version of GFA-DRAFT given away by ST-FORMAT. I want to print them on a Postscript printer (Apple Laserwriter IINTX). As there is no postscript printer driver supplied, I am using the Draft to Meta file converter program (also supplied by ST-Format). This produces a *.GEM file.

So far I have been able to inport these into TImeworks & print them off,but sometimes the drawings get reflected in the X & Y axes (usually if they are landscape orientation). Timeworks has a picture import facility, but it specifies GEM draw or EASY draw as the available options. Therefore I assume that it cannot handle generic Meta files.
Am I correct in this?

I have found a program om a.a called MFPS. This is a Metafile to Postscript converter, but again it was designed to work with EASY draw 2.0 & some other programs, not as a general Metafile processor. I have not got it to print off so far (I have just used the -f option),the laser rejects the file as it claims it has invalid commands.

Is there some easier way to print the files?

Regards

Gerry O'Rourke

: run, but the father falls asleep, why?

MiNT uses a blocking fork() (or Pfork()), so that explains why the parent
falls "asleep" in this case (read the manual page for Pfork()). You can
still start a background task running in parallel is you start it as
a separate process (with Pexec()). (I may be wrong here...)

You will get a lot of trouble with this approach, because:

(1) v_fontinit isn't officially documented and
(2) you are using Line-A.

Please use the normal GDOS interface (vst_load_fonts, vst_font and
so on) instead (at least if vq_gdos returns TRUE).

There are VM systems for the TT under TOS 3.xx -- most are from Germany.
There is no VM support in MiNT, true, but it's not far away. The 8K memory
page system and memory ownership concepts are exactly the sort of basis
required for VM. I imagine that such an implementation is a matter of time
for Eric Smith (obviously depending on his other priorities).

Pfork() is blocking in the current versions. This will go away some day.

> - Psignal(): I used the Psignal() call to install a Talarm routine. It
> looks something like this:
>
> func()
> {
> /* code */
> Psigreturn()
> }
>
> Psignal(14,(*func)())
> [...]

This code is wrong. It should look like this:

```
func()
{
/* code */
}

Psignal(14, func);
```

Your code does call the signal routine instead of passing its address to Psignal().

Also, you only need to call Psigreturn() if you plan to make a longjmp() out of your signal handler. If you don't want to do that (i.e. the signal handler shall return normally), you _must not_ call Psigreturn().

The expansion connector definitely has only 16 data lines.

The expansion connector must have more than 24 address lines, otherwise you
would only be able to address 2Mb (less addreesses used by existing hardware)
of anything connected to it when the full 1] 4Mb of RAM is fitted (in which
case it would be mega-crippled).
However, if the address lines have to be taken from the expansion bus,
doesn't this remove any chance of being able to add memory that can't be
interrupted by video refresh?

All the set colour functions of VDI and the work_out[] value giving the number of colours are currently signed shorts - are they *unsigned* shorts in TOS4? If not how are 65536 colours supported by the VDI?
Has a function been added to VDI to return the colour index that best approximates to a given RGB value? If not how do you write a multi-tasking program which uses a specific colour for something (Obviously changing the palette is not a good idea)? Even better, are there two functions:

int allocate_colour(int handle, int red, int green, int blue) - If the RGB value specified already exactly matches a colour in the palette then return the index of that colour and mark it as used by 'handle'. Otherwise set a colour that is not being used (ie. not been returned by this function, or if it has, been returned by free_colour) to the given RGB value and return it's index (again marking it used by 'handle'). If all the colour are being used then return the best approximation from the colours available and return it's index (marking it used by 'handle').

void free_colour(int handle, int colour_index) - Mark that colour as no longer used by 'handle'. This function is automatically called by v_cls_vwk with all the colour_indexs allocated by 'handle'.

Without something like this Multi-TOS is going to get into a bit of a mess with colours.

- Leo

It's nice to see a reasonable technical discussion on the Falcon/A1200 thread between people who have a notion of what they are talking about.

(For a change!)

: With fast ram, the processor will run at full speed. Can the same be
: said of the Falcon?

Well, a fast RAM add-on card for the Falcon should be possible
(at least I hope so because splitting the bus seems to be
A Good Idea), and there you are: No contention. But you're
right when you point out that fast RAM is a standard (=built-in)
concept in the A1200 hardware while in the Falcon030 it's not.
But then, a processor with built-in MMU is standard in the
Falcon030, but not in the A1200 ... :-)

Note that GEMDOS actually supports multiple kinds of RAM (such
as chip and fast RAM), as does the Amiga Exec.

: We complain about GEM, because you complain about Workbench.

You're comparing apples and oranges again! GEM is a complete
GUI, but Workbench isn't. It's just the "equivalent" for the
GEM Desktop, while Intuition is GEM's counterpart.

There are two sets of connectors on the motherboard divided into a 50 and
30 pin conenctor in each set. One of these is the "processor direct slot"
which has 24 address lines, 16 data lines, and all of the bus-control
signals. The other is the RAM connector, which has 32 data lines and I don't
know how many address lines, but probably only 24. I would not consider the
RAM connector an "expansion" connector since there is no ST RAM on the
motherboard. I.e., it is not an expansion, it is a required part of the
basic system.

Apparently all of that DMA is now handled by the blitter. Don't know its
addressing limitations either, but I would guess 24-bit again.

>The Falcon supports PAL? Good, can anybody else confirm this.

Yes. In fact the first two Falcons I got my hands on were both European/PAL machines. Unfortunately, although the ROM contains full support for all the various countries, and you can save your "localization" setting in the battery-backed configuration RAM, the composite video is still specific to either PAL or NTSC, not switchable. (Actually, you *can* switch between PAL and NTSC in software, but the machine still has only one color-crystal, which will be either 4.43 MHz or 3.58 MHz. So my UK Falcon can produce NTSC video, but it's NTSC 4.43, not NTSC 3.58... Likewise, my US Falcon can produce PAL video, but it's PAL 3.58 and not 4.43....)
>
>With fast ram, the processor will run at full speed. Can the same be
>said of the Falcon?

Yes, of course. That's like saying "with a SCSI-2 port, the A1200 can use any peripheral imaginable" though. Also true, but in both cases, neither machine has the support in the basic model...

Just a little side-comment on incompatibility and games - I was quite pleased to see that DungeonMaster runs on the Falcon, despite the digital sound effects and floppy-based copy-protection. It shouldn't be too much to expect well-written software for your machine, even well-written *game* software....

Nope, it appears that the Falcon supports both 5-5-5-1 and 5-6-5 RGB
modes - the 16'th bit can be either an extra bit of resolution for
the green (highest visual acuity) or the Genlock control bit.

>all the re-wiring, (expensive) cables, floppy&HD placement... Yack...

Admittedly, the last time I saw the insides of a Mega ST was over a
year ago when Dave Small and I demonstrated the SST030 board at the
Detroit/Windsor Atari Fest, but my impression was that the board was
quite similar in size to a full size '386 motherboard...

I have a nice little mini-tower PC case right here ($69 including a
200 watt powersupply) that would almost hold my full sized 520 ST
motherboard.. I was assuming that the Mega ST board would fit inside
quite easily.

Obviously all the connectors on the boards would have to be desoldered and
moved to the back of the case, and probably new openings cut in the metal
case to fit them, but the disk drives should fit in the pc bays easily
enough, and there should be plenty of room for host adapter boards
(although again, the mounting points might be a problem).

From the sound of your message though, it appears that you've already
tried this modification, so if that's the case, I'll defer to your
experience... (but I still think that if I could find a *cheap* Mega,
I might just give it a shot..)

I fail to see the comparison. A SCSI-2 card could be added to the A1200
via the expansion slot. Commodore approve of this. Adding fast ram to the
Falcon is not so easily accomplished, at least in a manner Atari would
approve of.

I'm pretty sure some in the UK said it could be configured to come with 1meg
chip and 1 meg fast RAM, but

a) whether the original poster was correct
b) my memory serves me correctly
c) that the fast ram is truly "fast" or just remapped...

Is all up to speculation unless someone "in the know" (hint: George?) has
some true "facts".

Well this raises a matter that has been a concern for me for
a while. I'd like to know what the colour encoding is for the various
Falcon screen modes. Historically, the ST started with 3-3-3 and
the register codes bitwise were MostSigbit, NextSb, LowestSb, but
when they upgraded the STE with 4-4-4, they rotated the bit order to
LeastSigbit, MostSigbit, NextSigb, LowerSigb. I didn't hear about this
for the longest time. I almost upgraded to an STE. When I heard
the bit order I said "something colourful" and decided against it.
Among other things I occasionally write minor data converters. I
sometimes call them "bit twisters" or "bit scramblers". In the case
of the STE, "bit scrambler" would be just about the right
description. :-)

4578. MiNT distribution to be on a.a RSN

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-28 14:32:21 UTC
From: sjg@phlim.ph.kcl.ac.uk
Message-ID: <1992Nov28.143221.12695@sol.ctr.columbia.edu>
Source record: 41774

Well, people, the MiNT distribution kit has been uploaded to a.a.u.e
and will presumably be made available fairly soon. The first update
to the kit will also be uploaded (probably) on Monday. This will be
the replacement for Gcc 2.2.2, the sharable gcc 2.3.1 for MiNT.

There are 3 directories, 'Distribution' contains the zoo files. 'Docs'
contains a PostScript document, and the Ascii text for that document.
(For those without access to ghostview, dxpsview or similar). The
last directory is 'Updates', wherein you will find any updates to the
kit.

I've been made aware of TT-specific binaries for MiNT. I'm going to
try and incorporate those, although I have no way of testing any
particular conformation. I shall place TT-Specific binaries into a
fourth directory called 'TT' (such originality!)

Finally - I'd appreciate some feedback from anyone who's either used
or is using the kit. Comments, Dislikes (these especially), and (of
course) Praise are all welcome.

Simon.

It doesn't help because Atari developers haven't had
tools or conventions worked out to support anything but
general purpose RAM. In theory, I could take my old STf and
blow it out to 8 Meg RAM. But if I run a paint program, and
it happens to declare data space in the "Fast RAM" zone, and
treats it as screen RAM, I'll never see it. The Amiga developers
(and users) are ahead of Atari people in this respect simply
because they've been dealing with it since the beginning.

As of version 2.nn Workbench, I don't think that this comment
is justified. That could be a pretty long discussion topic
in itself.

Incidentally, I still have my 1040STf with TOS 1.4, and I
now also have an Amiga 500 with DOS 1.3. If I get the money together,
there's a good chance I'll buy one of the new machines. My current
feeling is that I'll finally ditch the 1040STf and get a Falcon,
but there are huge "ifs" there -- mainly to do with money.

I heard Jim Allen discussing the possibility when the Mega came out,
and, at the time, he was told that there was a certain time window where
a board on the Mega slot could ACK after the bus error and get around
the error handler, or somethng to that effect. Thus, he said, a second 4
meg with a second MMU was possible, but he didn't seem to think the
cost/demand ratio was good enough to warrant building any.
I may have the explanation garbled, as I'm not a hardware engineer,
but that was the gist of it. I understood that a similar mechanism is
what allows the Moniterm board to work.

>I've heard of attempts to circumvent this, but have never heard of a

I never heard whether he bothered pursuing the idea.

>(By the way.. anyone who would pay $450 for a new MMU chip should
>contact me for a wonderful, limited time opportunity to buy natural
>Wetlands properties in the South Florida swamps..)

I think the chip mention was a custom designed replacement for
Atari's mmu, and with a limited production run, and design costs to
recover, this doesn't seem unreasonable. There was a board from Germany
that allowed you to go to 12 meg on a Mega, that came out around the
same time as the TT. I beleive, in North America at least, that it cost
about $100 leass than a new TT. Small wonder it didn't catch on.

Source record: 41786

We are having problems implementing vertical cursors in a graph program we are writing. We want to be able to position a vertical line using the mouse - when it in the correct position (on a graph), it should be possible to fix the cursor on the screen with a button click. As soon a line is fixed we need a new line following the position of the mouse so that it is possible to fix that and calculate the distance between the pair of lines. After setting a series of lines, all the coordinates have to be written to a file.

We have tried to work it using the mouse coordinates with LINE_A functions by drawing a line at the last position of the mouse to erase the old lines left by the cursor but this doesn't happen and the screen fills up with lines as the mouse is moved - this is quite fun but it's not what we need. It would be good to be able to use the right mouse button also but it doesn't appear possible to directly request the status of both buttons - only one or the other. If this is the case, is there an easy way round?

The program is being written using PURE-C on a 2 meg ST. The documentation we have for LINE_A functions is not very good. I know of a few programs using cross-hair cursors so our problems may be easy to fix ... we would grossly appreciate any help given. (email if possible).

Mark.

You need a null-modem cable, not just a modem cable that is female on both
ends. This is because you need the send of one end to match the receive
of another, not the send to match the send. A null modem cable should be
available at a computer store, if not please make sure that the cable and
connectors are properly shielded.

If you need the wiring for a null-modem cable, check with a local computer
club. I am not sure of the wiring, but basically send goes to receive etc.

Memory-protection has been a working feature of MultiTOS for several months now. Yes, amazingly enough Atari is actually taking advantage of the new features available to them.

==========
Just a quick point; The Service Manual for the MegaSTE shows that the
MMU has 2 additional address lines for 16MB. The manual also refers to a
VME memory board made by a third party. I have never seen the memory
board myself...

It sure would be fine to get some of the developing team of falcon to
give us the facts, but.... (read on)

>
>I give both these chaps a TEN...
>
>I am also fed up with these Atari dumbos that know very little about the
>Falcon, but still wish to argue the point, to me they make them selves
>look stupid..

The reason that no-one who knows don't speak up is that Atari have a fearsome
Non Disclosure Agreement (NDA) everyone have to sign before receiving anny
real information, and all information is 'confidential'. I feel policy this
is a bit paranoid, but as I have signed the NDA I surely will not (and cannot
afford to) break it. This, I would guess, applies to the developing team
as well....

For those who need information from a relativly reliable source, you should
definitively check out the german magazine 'ST Computer', and NEVER EVER
trust ANNYTHING (but perhaps onhand reviews) in anny UK magazine!!!

To make a "minimal" null modem cable wire pin 1 to pin 1, pin 2 to pin 3,
pin 3 to pin 2, and pin 7 to pin 7.

This will cross over the transmit and recieve data lines.

I doubt that it can be much of a pain to put the mega boards in full
tower cases. I put my LARGE 1040 ST board in a tower case, together
with a 50 meg drive, a DD DS floppy, and a four-meg RAM upgrade. I ood
used inexpensive ribbon cable to run the original (I desoldered them)
plugs and sockets out to the backplate, and I bought ONE new cable--
$ 4.99, a universal joystick extension which I used for my detached
keyboard (the original keyboard mounted in the original 1040 plastic
case, suitably cropped. Now I have a very reliable power supply, and
the (admittedly) ludicrous size of the box is unimportant because it
stands on the floor by itself. The floppy and hard drives slipped
neatly into the standard bays, and I rewired the rear reset so that
it is now controlled by the friendly front-mounted tower reset switch.
All in all, it is about as cheap as making your own external hard
drive unit, and only a bit more work! But Falcons weren't available
when I put that unit together. . . .

Does anybody know how widespread the use of XBIOS routines is amongst proper (non-games) programs. Specifically does say a program like Cubase/Notator use the XBIOS routines to communicate with the MIDI hardware, and the timers within the MFP chip.
The reason is that I am trying to figure out if ONLY the XBIOS routines need to be changed, so that another 68K computer (I won't mention the name here) can run programs FULLY!.

If anybody has any suggestions them post 'em (preferable) or e-mail direct.
Thanks in advance.

>it takes "3-pixels" to effect a complete color change - take
>the best case 1280 pixels (a bit more with overscan) divide by 3 and
>you get 420.

So you get 420x480, with each pixel being a 3-pixel bleed that is the colour
you want for the last 1/3 of the pixel.

Gross.

I have seen HAM mode on an Amiga. It is ONLY useful for displaying
digitised images. I think only about one or two applications ever
featured dynamic HAM mode USAGE, although plenty used it for static
image display.

The Falcon's "True Colour" mode will NOT perform as well as 1280*480 HAM-8
on digitised images. It will however, have far more diverse and flexible
applications. For example, simply having windows with HAM mode is an
absolute nightmare... even looks like a surreal nightmare when you start
dragging things around!!!!! BLEEEEEEDO!

Just as an example, the Falcon ships with a True-Colour game, I believe
(although it's something like BreakOut - I know nothing more).

> build between ST's 23-pin connector and SCSI-plug?

You'll also need to get your hands on a host adapter of some sort
(I heartily recommend the ICD product!) since the DMA/ACSI port is
not true SCSI. You'll connect the host adapter to the ACSI port,
then connect the Adaptec 4000 to the host adapter, then connect
the drive to the Adaptec. It'll work very well (that's how I ran
my system for many years...) although it won't be blazing fast.
An interesting note: The ST can handle up to 8 SCSI devices, meaning
you could have up to 8 Adaptec controllers on your system at any one
time. Each Adaptec can handle 1 OR 2 MFM mechanisms, so you could
theoretically have as many as SIXTEEN hard drives on your system at
any one time, all of them online and ready for simultaneous use. Not
bad for a "game machine" huh? :)

You can't do real time MIDI properly (ie play/record multitasking with GEM, no lossed notes) without hitting the hardware from you own custom interupt code.

While I haven't disassembled Cubase/Notator, I have disassembled several PD/Shareware/Demoware sequencers and all of them (except one) hit the hardware pretty viciously. The exception is the Cosh sequencer which does things through XBIOS and has serious timing/note lossage problems as a result.

The XBIOS midi handling routines are NOT used by programs such as Cubase, because they have several bugs which come to light when you start passing large amounts of data through them (missing bytes, timing errors, etc), so Cubase accesses the port directly. Steinberg have been VERY careful how this is done however, to ensure compatibility accross the Atari range.

>(2) you are using Line-A.

Oops, didn't know that. That's why it took me some trial and error
to find out the right way to proceed :).
BTW, I did check your book "Das Atari ST Profibuch" and if I remember
correctly the v_fontinit() was in there. But, I have to admit, the
print I own is one of the first releases.

>Please use the normal GDOS interface (vst_load_fonts, vst_font and
>so on) instead (at least if vq_gdos returns TRUE).

I would love to, but both myself and the target group (the users
using the program) are unlikely to have gdos running.

Is there any public domain gdos available?
Also, aren't there any ROM library routines to handle these font
issues in a portable and proper way?

It must be several months ago now that Ian mentioned HSC 1.4 with
Gemfast 1.8 would be out very soon. I haven't heard anything of HSC or
Ian himself since then. Does anyone know what's happening?

From: cpr@dde.dk
Message-ID: <1992Nov30.152711.4226@dde.dk>
Source record: 41702

Following the thread, I would like to know if someone with DSP and Dolby Surround knowledge could clarify the possibilities of using the Falcon as a Dolby Surround decoder (prologic or whatever)?

As far as I know it requries stereo input and stereo output + 2 x mono out (one for effects front channel and one for the rear channels). I believe it would require a little extra hardware for the extra pair of output sockets (unless you can use the original stereo sound directly, and then just use the falcon output for the 2 mono-channels). To my (somewhat limited) knowledge I think it should be possible, but maybe I have ignored some important facts, such as the mighty Dolby Labs having some kind of copyright on the needed algorithms and so on.

I know that this type of application might have a smaller market than e.g. the very exiting voice phone system mentioned elsewhere, but it would make me want a Falcon even more.

>mmartin@neumann.une.edu.au

I've posted this since I feel other people might be interested:

Don't use A-Line. For a start it's not upwardly compatible, but of more relevance to you is that:

a) It's badly documented (as you found out)
b) The extra complication of using it is not worth it in your case.

So, use the VDI instead. It really is much easier. I did a similar thing once, for a Mandelbrot zoom function (it was cross hair cursors, actually). The pseudo-code is as follows (from memory)

```
Set VDI XOR drawing mode
Hide mouse
call get_pos
call get_pos
Show mouse
Reset VDI drawing mode
return

get_pos:
repeat
Get mouse position
```

```
Draw cross hairs
repeat
Get mouse position and status
until mouse has moved
Draw cross hairs at old position (so erasing old lines)
Note new coordinates
until mouse button is pressed
return new coordinates;
```

This is "modal" cross hairs, of course. It gets far more complicated if you want to let the user access the menu bar etc. while using the cross hairs.

Nothing quite like displaying complete ignorance in front of billions, eh?

>>It is in 768x576 PAL mode.
>
>The Falcon supports PAL? Good, can anybody else confirm this.
Since the machine does have a TV-modulator in German machinery, it does
support PAL.

Anyway, now for something less contentfree:

Some people suggest that the 16-bit bus is due to 'compatibility' with the
ST. I don't quite get where a 32-bit bus would leave software incompatible.
The only case I could make up is, when you are writing a LONG into a
memory mapped chip, like one does to access the PSG quickly. Me thinks
a 16-bit bus to memory mapped I/O space would have been better then.

Nat!

4613. 1.44 meg floppy drive conversion

Newsgroup: comp.sys.atari.st.tech
Date: 1992-11-30 18:23:27 UTC
From: "Gerry O'Rourke"
Message-ID: <1992Nov30.182327.24251@nt.com>
Source record: 41699

Hi all
Last wekend I tried to modifiy to my ST to use 1.44 Mbyte high density drives. I followed the instructions given in ST FORMAT (I corrected the errors on the 1772 pinout) by cutting the trace to pin 18 (CLK in) & attaching a wire from pin 39 of the shifter.

My drives are teac HF-235's & I used these to replace the old single sided drives when I changed to DD disks, I felt that someday I might want 1.44 drives. I know that to use these properly you have to use logic to select the clock rate depending on whether the disk is a DD or HD type, but I only wanted to find out if my 1772 controller is able to function at 16Mhz.

If it is, then I will put together a circuit to select the clock.

I knew from previous postings that the chip either works or not. If it does not, then get an AJAX & use that.My problem is that it seems to work.
I can select drives, but I can't read any disks. I have tried changing the step rates using Fcopy,I can then format, but not properly.

I tried changing the jumpers on the drive & eventually arrived at a situation where I could fromat from the desktop, but could not write to the disk. When I tried to read the disk on an IBM, there were errors.
Most of the errors seem to related to seeking tracks.

Has anybody been in this situation before & successfully sorted all technical problems to produce working HD drives?

Does the AJAX always work?

Does the kit supplied by the Atari Workshop get around this problem ?

I realise that the WD1772 was not meant to work @ 16 Mhz, but I have read that the 1772-02-00 version usually does, while the 1772-02-02 usually does not. I have the 1772-02,where does that leave me?

Please post any answers, as there may be others in this boat.

Regards

Gerry

Well it would be gross if they weren't 1280 pixels to start with,
but since they are it works quite nicely. Also, this is talking
about worst case, and there is still the escape of using the color
table base values to better approximate abrupt changes in one
pixel. This can get you to 1 of 64 arbitrary colors in one pixel,
which can then be tweaked in the following pixels if needed.

I'm not going to claim that HAM is the best thing since sex, however
it does no harm to try to understand how it will perform in real-word
applications relative to 15/16-bit "true-color".

> absolute nightmare... even looks like a surreal nightmare when you start
> dragging things around!!!!! BLEEEEEEDO!

Well, unless something has changed, having true-color in one window on
on the Falcon in "true-color" will force all windows to the rendered in
"true-color" in whichever scan rates/interlace supports true-color mode.

> Just as an example, the Falcon ships with a True-Colour game, I believe
> (although it's something like BreakOut - I know nothing more).

There is always at least one Game to supper each strange mode, but I
don't know if there will be more. There are one or two HAM games, but
they are of no consequence in the general order of things.

Mostly, either mode will be used for paint-programs, image rendering/
dislplay and "cool demos"...

Ok, in the next few days (ie when I get around to it) I will be uploading
some source code to do this in order to email it someone, its not a truly
optimised piece of code in some sense, but it does work and is designed
to start by a suitable call to one routine and switched off by a call
to another routine, it will then allow the extra top and bottom to be
useable.

The question is: Shall I post it here?

Mark

If all access to the blitter is via system calls, then the operating system can "validate" the addresses involved. Half of the memory protection game is keeping the user software from violating memory it doesn't own, but you also have to put work into validating addresses and lengths passed to system calls or placed in structures.

From: dclemans@mentorg.com
Message-ID: <1992Nov30.225705.14071@news.mentorg.com>
Source record: 41706

In current versions of MINT, can a signal interrupt a system call?
For example, if a process is waiting for a read on a FIFO, can
the process also use Talarm to periodically break out of the read?

Also, is there any real "non-blocking" read method in MINT,
especially for FIFO files? I've tried some experiments with both
fcntl and the flags passed to Fcreate to create the FIFO, but
neither seemed to have any effect.

(Basically I'm trying to get the TNET tcp/ip networking package
recently posted to the Minix group to work with MINT.)

Thanks,
dgc

4619. Colour bit encodings (was Re: Falcon '030 BUS: 16 or 32 bit?)

>LeastSigbit, MostSigbit, NextSigb, LowerSigb. I didn't hear about this
>for the longest time. I almost upgraded to an STE. When I heard
>the bit order I said "something colourful" and decided against it.

Think about it for a while... it's quite clever.

Imagine an old ST program... it sets a colour to "777" (hex), expecting
white. If the STe had made the 4th bit the most significant, then this
would have been a middle grey - YUCK! However, by making the top bit the
LEAST significant, "777" is just ever-so-slightly-darker than the brightest
white, "FFF".

So see, the bad computer is not the STe, it is the ST for using such
an unthoughtful encoding. Remember the 8-bits? They ignored the least-
significant bit for luminance... until the XL's finally came along and
used that bit (I think).

The correct way to specify colour on the ST would have been with a
32-bit colour index:

xxxxxxxx HMLxxxxx HMLxxxxx HMLxxxxx

H=highest, M=medium, L=lowest

Then, everyone would probably have complained anyway about how
"0xE0E0E0" was white rather than simply "0x777"....

Note however, that the VDI uses a 30-bit colour encoding (0 to 1023 for
each of R, G, B).... that should never go out of style... until the human
eye evolves a bit more.

I believe there is a German company already working on this product. Probably the major cost will be getting the license from Dolby Labs. The encoding is quite simple though, and it would be easy to write a Dolby-compatible decoder without going for the Dolby stamp of approval, but that would make for quite a marketing headache.

For the full Pro-Logic performance you would need two more audio outputs, because the Pro-Logic circuitry subtracts the surround and center info from the original left and right channels. Skipping that step would give you the equivalent of regular Dolby Surround, with the addition of a center channel.

Anyway, I suspect that there will soon be enough uses for the full 8-channel audio that you'll find DSP port expansion boxes from a number of sources. It would be pretty simple to make a box that just has 8 RCA jacks and a pass-thru DSP connector... (Tho now that I think of it, it should properly have 16 jacks, 8 in and 8 out, and will need at least line-level amplification for the outputs...)

Yeah sure. And on those 16 drives you can have up to 24 * 16 mbyte
partitions (384 Mb). Probably better to buy one 330 Mbyte drive.

:
: >it takes "3-pixels" to effect a complete color change - take
: >the best case 1280 pixels (a bit more with overscan) divide by 3 and
: >you get 420.
:
: So you get 420x480, with each pixel being a 3-pixel bleed that is the colour
: you want for the last 1/3 of the pixel.
:
: Gross.

If you were trying to use HAM8 mode for technical drawings, then this bleeding would be bad. But why wouldn't you use some other mode on another screen?

If you were trying to display some real world image, then HAM8 would do a better job than any screen mode that the Falcon has. Real world images don't have stark contrasts, from black to white. Try displaying images with skintones and see which is better.

: I have seen HAM mode on an Amiga. It is ONLY useful for displaying
: digitised images. I think only about one or two applications ever
: featured dynamic HAM mode USAGE, although plenty used it for static
: image display.
:
: The Falcon's "True Colour" mode will NOT perform as well as 1280*480 HAM-8
: on digitised images. It will however, have far more diverse and flexible
: applications. For example, simply having windows with HAM mode is an
: absolute nightmare... even looks like a surreal nightmare when you start
: dragging things around!!!!! BLEEEEEEDO!

Amiga uses screens. You don't need to run Workbench on a HAM screen.
My text-editor runs in a 4-bit-plane deep screen and the terminal emulator runs on a 2-bit-plane screen. I can easily flip between the processes and and slide the screens so both are partially visible. My CLI/shell sits on the workbench screen.

Care to name any of these "diverse" and "flexible" applications?

Do you have to reboot to change screen modes on the Falcon? Are the true displays on a separate screen or can you mix modes withing windows?

: Just as an example, the Falcon ships with a True-Colour game, I believe
: (although it's something like BreakOut - I know nothing more).

Well, you can get a 24bit Karate game for the Amiga...

: Warwick

>is very low, and it is quite easy to program an ACSI transfer.

Indeed, the SCSI exec core is very small (some 30 lines). However, there
is a big pitfall. The DMA chip will only move data to/from main memory in
16-byte chunks. A MODE SENSE, for example, will return less than 16 bytes
from many devices. You then need to request some extra bytes (INQUIRY is a
fine command for that) without clearing the DMA FIFO first. As a result the
data you want is then pushed into the receive buffer, but it will be some
bytes more than you expect...

>ACSI just suffered from some flaws: The hardware interface was
>not very stable (no buffering etc.) and the DMA chip cannot handle
>transfer speeds exceeding ~1.5 MB/s and transfer sizes > 255*512
>bytes. Remember that at the time of ACSI's design, most affordable
>hard drives were small (~20 MB) and slow (~500 KB/s).

Yesterday I found out that this is probably what makes my Wangtek 5150ES
tape drive hang on reads. It can transfer up to 1.8 MB/s... I'm now
considering to put a 100ns delay in the REQ- line on the ICD host adapter
to slow down things. I'll just hook hup a logic analyzer to get hard
evidence.

Much better in the sense that it can do more things, perhaps. Much better
in the sense of it sounds better on normal applications and games, debatable.

Please note that "professional recording" means 24-bits, which the DSP
might be able handle with appropriate (read expensive) CODEC adapters and
big disks, but not the included 16-bit CODEC. The broschure makes the
interesting claim of "better than CD" sound. Maybe this referes to the
50 KHz sample rate, but it's not clear whether Atari has managed to
implement a "CD quality" signal/noise ratio in their Analog interface.
They're due some kudos if they have.

Yes, why would you use a true-color mode for general use? For games,
maybe but if it requires abusing twice as much data to animate the
game it's only going to get token use.

Well, mucking up copper lists doesn't "crash" the system, it just trashes
the display. It reflects one common technique for screwing with software
internals that has broken games since the relase of the 2.0 software and
is not peculiar to the A1200.

4628. 3rd party floppy on Atari 1040STF?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-01 08:51:06 UTC
From: wang@hp4at.eunet.co.at
Message-ID: <1992Dec1.085106.6108@hp4at.eunet.co.at>
Source record: 41712

Since the floopy drive on my Atari 1040STF isn't working anymore,
I was trying several 3rd party drives (Epson, Sony both 720k). But there
is no way to get them running. I jumpered the drives as drive '0'
but turning the Atari on the motor runs permanently and the driveselect LED
is on. I assume that there must be changed something somewhere. I don't know
anything about Atari internals (I'm just using it for musicpurposes).
Help is appreciated!

Thanks a lot,
Michael

I don't know the precise details of dolby surround, but given my rough know-
ledge of the (en/de)coding process, I'd say it would be a piece of cake.

>As far as I know it requries stereo input and stereo output + 2 x mono
>out (one for effects front channel and one for the rear channels). I
>believe it would require a little extra hardware for the extra pair of
>output sockets (unless you can use the original stereo sound directly,
>and then just use the falcon output for the 2 mono-channels). To my
>(somewhat limited) knowledge I think it should be possible, but maybe
>I have ignored some important facts, such as the mighty Dolby Labs
>having some kind of copyright on the needed algorithms and so on.

All these points are basically sound. It should be easy to add more analogue
I/O channels onto the DSP serial port - you are correct that Dolby surround
decoder is a 2-input, 4-output device. I am sure that Dolby have got copyright
on the algorithms, but there can't be any restriction on writing your own, for
your own interest, provided that you don't sell it, and you don't call it
Dolby - but please note that I am NOT a lawyer :-) (thank goodness...)

: and is there a chance that on the finished multitos disk access will
: not always halt the whole system (including processes that are not
: waiting for the disk...) like now with MiNT/GEMDOS?

It's just a matter of the drivers. I've been investigating MiNT's
capabilities in this respect lately, and I think it's possible
to extend my disk driver in such a direction even with the
current version of MiNT.

: currently with TOS+MiNT the main limiting factors seem to me i) sloow
: and bugged GEMDOS

There's nothing that stops us to write a new GEMDOS.XFS for MiNT!
With MiNT loadable filesystems, now's the time to do that, finally.

and ii) GEM eating up *much* more CPU time than
: necessary. (just put `top' in a toswin window and you'll see)

Well, the AES gets all CPU time that other processes do not
eat up. Maybe that's the reason why the AES/GEM CPU time percentage
seems so high. Just guessing.

>board myself...

>--
>Russel Mar (bbs.ruscal@tsoft.sf-bay.org)
No answers but more questions.
What are the decoded address ranges of the GSTMCU I/C outputs in the STE:

pin output used address range
L14 ROM0 no ??
N15 ROM1 no ??
K13 ROM2 XROM2 $E00000->$E3FFFF Tos 1.6, 1.62, 2.06
K14 ROM3 XROM3 $FA0000->$FAFFFF Cartridge port
L15 ROM4 XROM4 $FB0000->$FBFFFF Cartridge port
J14 ROM5 no ??
J13 ROM6 no ??

The interesting thing is that the Tos ROMS are 1Mbit devices but the
I/C holders are 32 pin which means that 4Mbit devices could be used if
the wiring is changed!

This is the same symptom you get when the cable to the floppy is twisted.
The mechanisms I've seen have "reversed" connectors n them, compared to the
ST. Make certain pin 1 is cinnected to pin 1... etc. All that is needed is
generally to flip the cable and plug it into the drive. No re-making of the
cable unless it's just too short.

I'm trying to ubgrade a TOS 1.4 system to high density floppies...
So far, the Ajax chip and Epson 1.44MB mechanism are working flawlessly at
720k. I'm worried about the steprate when I double the clock rate, and the
possible loss of 720k functionality!

========================================================================
= THE SIMPLE(ISH) GUIDE TO BASIC SOFTWARE OVERSCAN ON THE ATARI ST =
= (With notes for the wise & learned in the darkest arts of assembly) =
========================================================================
=30/11/92=
==========
Here it is folks, as promised, here is an intro. to software Overscan.
This article first appeared in the September 1988 issue (#31) of STWORLD
(now sadly gone to dust), and is mostly the work of :

SIMON MARSH of Ladybridge, Bolton, England.

I don't have a complete contact address for him, but if anyone knows him
or knows of him, respect where respect is due - and this is to my knowledge
the first (only) documentation of software overscan. Enough of my senile
ramblings, on to the article (full source code follows after the body text).

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
This may be the first in a series on articles on obscure programming facets
of the ST. Topic's I thought may interest include .GEM files (how, why, etc)
, .IMG, GDOS, sprites & animation....?
If any interest is shown, I'll dig some more out of obscurity......
CRAIG GRAHAM.
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

------------ATARI ST SOFTWARE OVERSCAN INTO THE BOTTOM BORDER--------------

Richard Seel, ex-editor of STWORLD Programmers Clinic, writes:-

To end with, something rather clever (but silly)! Simon Marsh of Ladybridge,
Bolton, has sent in a listing which allows you to display an extra few lines
on a colour display (I don't recomend that you try it with a mono monitor).

It works by switching the scan rate of the shifter chip from 50Hz to
60Hz on the last line of the scan. This makes the chip think that there are
more lines to display, and so it carries on. At the start of the next new
line the shifter rate is returned to 50Hz and it now carries on writing
lines until a vertical blank interupt occurs. Using this technique it is
possible to display up to 40 extra screen lies (about five lines of text in
low res.), depending on the monitor or TV set.

Simon points out that if you intend to alter his listing for your own
use, it is the switch back to 50Hz which is critical:

Simon Marsh writes:-
```

Switch back too early, or too late, and distortion occurs. I have found that a MOVEM to stack variables used in the HBL routine, and then the switch to 50Hz provides the right timing. It must be noted that when using the routines, programs will slow down by a considerable amount due to the processing needs of the HBL (NOTE by Craig - HBL=Horizontal Blank Interupt as used by Multi-pallete programs). Using similat routines though, I have managed to display 17 colours a line over 250 lines (I think that is about the maximum before th VBL), which is a staggering 4250 colour changes every 50th of a second, and still manage to do animation & graphic displays - all at the same time!

You are now probably thinking there must be a drawback - there is. Since the shifter is switched to 60Hz, it finishes the last line slightly faster than it should when it is in 50Hz. The result is that the shifter doesn't display the last 16 or so pixels at the very end of the right-hand side of the bottom of the logical screen, leaving them the same colour as the border.

Also, it might be thought that the extra 50ish lines should start at screenstart + 32000, but they don't; they actually start at screenstart + 31998, again due to the fact that the last line was in 60Hz. This means that the lower border graphics are on a different 'plane' compared to the rest of the screen, making it more difficult to swap graphics between the two. Also, normal Line-A or GEMVDI/AES graphics commands will not work in the lower border, so your own routines must be written. Another thing is that, since the timing must be perfect, the technique is greatly affected by key presses and mouse movements that interupt the HBL.

(Craigs Note :- I think it should be possible to set some masks to stop the problem with interupts detailled above, but haven't tried it myself.)

And what is the point of all this screen activity? Well, even Simon doesn't think it has any practical purpose - but I suppose someone might come up with some kind of use for it.

----------END OF ARTICLE TRANSCRIPT----------

There follows an editted and corrected version of the assembly language source listing which accompanied the above article. It didn't quite work as printed, so I've fixed one or two thing's and tidied it up a bit. This listing is only tested by me on my TOS 1.0 machine (circa 1986), so there is no chance of me fixing bug's for anyone with other machines. I doubt very much if it will work on MegaSTE/TT/'s as it depends very much on timing (see above).

--------------------------------CUT HERE-----------------------------------

This program was assembled using Devpac 2 on a 1 Meg TOS1.0 ST, with &
without a hard drive attatched.

NOTE:To actually do anything constructive it is probably a good idea to
mess about with the dissable_loop: bit of the code so that you can
still use Keybd/mouse/joystick.

And finally, I have some sprite routines (hasn't everyone?) which
could probably be modified to allow sprites into the bottom border
'fairly' easily. I'll have a look at them before Xmas.

4640. Text input/display in GEM window

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-01 15:13:23 UTC
From: renfro@crchh610.BNR.CA
Message-ID: <1992Dec01.151323.7005@bnr.ca>
Source record: 41723

Does anyone know of any system routines (GEM/TOS/etc) to handle
'easy' text input into an window. This would be the kind of
input/display required for a word processor. I am working with
GFA Basic right now, but the question could apply to any language.
As far as I can tell, I have to code all the keyboard input handling
(ie what to do with characters, backspace, cursor keys, etc), the
word wrap handling, and display the results using a text or A-line
type command. This is turning out to be a lot of code. Anyone have
any better suggestions?

Thanks,
RandyH

4641. VGA Monitors on ST's in general

|> me anything at all on this subject?

Oh no, I'd also like to hear about this stuff, exspecially because I'm thinking
about buying one and later being able to use in at the falcon, if I'll ever
buy on. When considering that the VGA-monitors must be able to operate at
several frequencies (so to say: be able to display different resolutions
like the old CGA one) this doesn't sound very difficult, perhaps just
another connector or soemthing like this. Isn't it true that the VGA output
signals are also analog RGB signals? So where's the point?

>In current versions of MINT, can a signal interrupt a system call?
>For example, if a process is waiting for a read on a FIFO, can
>the process also use Talarm to periodically break out of the read?

Yes. When the signal occurs, the signal handler is called. If the user's signal handler does a longjmp(), then the system call (e.g. read) is aborted. If the user's signal handler returns, then the system call is re-started automatically. (This is the way BSD works, but is *not* Posix behaviour; Posix says the system call should abort in this case too, and return EINTR).

>Also, is there any real "non-blocking" read method in MINT,
>especially for FIFO files?

Yes. Do an Fcntl(fd, (long)O_NDELAY, F_SETFL) on the file descriptor after opening (or creating) it. Then Fread will return 0 whenever no data is available.

(O_NDELAY is 0x100, and F_SETFL is 4).

(Hi everyone. Yes, I'm back on the net; but I'll probably be posting only sporadically. We're rather busy right now working on MultiTOS and other stuff.)

>Ian himself since then. Does anyone know what's happening?

I've got a beta version of 1.4. I've had no problems with it. I'm sorely tempted to go ahead and release it, because Ian seems to have dropped off the face of the earth. Is there anyone in Boulder who can look him up? I don't even guess that I have his snail-mail address, though I will certainly check.

Maybe now that I'm employed I'll be able to get back on BIX, and get the lines of communication back up.

If I haven't been able to hunt him down in a couple of weeks, though, I may well put it up on a.a (or at least the binaries--there's still some source problems...I've got them, but they're mighty disorganized). I don't feel totally comfortable, but since none of the other beta testers have heard from him in a similarly long time (Chris, Scott, Steve, have you?), it looks like it may be the only thing to do.

Oh, well,

I'm only responding to the points on the Falcon's audio - which I know a
little bit about.

16-bit audio is the *standard* of what you refer to as 'professional
recording' - show me a 24-bit CD. The majority of all digital audio
recording and mixing/modifying equipment in use today by 'professionals' is
16-bit. No denying that 24-bit will be the new wave, but it isn't here yet
and it will be quite a while before you have 24-bit playback as standard
consumer equipment.

You are right that the internal 2 channel A/D-D/A circuitry of the Falcon
doesn't meet the quality standards of most CD (and above) equipment - fine,
neither does the analog circuitry in most CD-ROM players with audio
capability. BUT - I'm hoping some industrious developers out there will
build both 2 and 8 channel interfaces with 'professional' quality circuitry
for 16-bit audio at up to 50KHz sampling rate. I'd love to do my assemble
editing and mastering on a Falcon with a large SCSI-2 hard drive and a 2
channel external box (about $100-150), or do actual 8 track recording with a
larger disk and an 8 channel external interface ($300-350) - both of those
would still be significantly cheaper than *any* computer based digital
recording platforms or dedicated hardware available today. And they would
be easier in the 'plug-and-play' aspect than *any* computer based digital
recording platforms available today.

All this is speaking as a 'professional'....

>There are 3 directories, 'Distribution' contains the zoo files. 'Docs'
>contains a PostScript document, and the Ascii text for that document.

The ASCII text file 'readme.1st' has been added to the Doc (not Docs) directory. This version of the text file has line feeds at the end of each line of text, rather than a single carriage return at the end of each paragraph.

>bad for a "game machine" huh? :)

I guess that's not true because the Adaptec A4000 adapter
eats SCSI addresses 1 AND 2 so ST can handle only 4 of them.

Btw, this is not my problem - I'll never have enough
money to afford even four SCSI-things and can't even
think about 8 or 16 :)

4648. Re: why isn't there a completely recompiled TOS around?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-01 23:21:52 UTC
From: jensk@hpbbn.bbn.hp.com
Message-ID: <JENSK.92Dec1162152@hpbbrn.bbn.hp.com>
Source record: 41648

> Well, the AES gets all CPU time that other processes do not
> eat up. Maybe that's the reason why the AES/GEM CPU time percentage
> seems so high. Just guessing.

In the versions of BGACC (precursor of TOSWIN) that I have seen, the reason
for the high CPU consumption was plain. The main loop looked like this:

wait for GEM events (including TIMER event)
if anything other than a TIMER event arrived
process it

else (ie only TIMER event)
if there's data waiting on the pipe to the application
read it & put it in the window

loop

There seems to be no other way to simultaneously handle GEM events *and*
data coming in over a pipe, because the AES knows nothing of MiNT. Only
a MiNT-aware AES can help here.

Correct me if I'm wrong (I hope I am ...),

Jens.

What a load of crap. Maybe I'm looking to the wrong site for credibility on this issue, but this is utter rubbish and people should know it.

"Professional recording" means the kind of recording used by professionals. For the most part, that would be 1" analog, 2" analog, a very tiny number of 24-bit recorders, and a whole lotta 16-bit digital machines. I wonder if Prince, at his (analog recording + 16-bit mastering) Paisley Park studio, realizes that he's not a professional? He should've asked George!

Until there are a few thousand 24-bit CD players out there (current count: zero), 16-bit digital is all pros need. Don't listen to this weenie; he's lying to you.

> The broschure makes the interesting claim of "better than CD" sound.

With the standard $799 machine, highly doubtful; most people don't need that. For studio-quality s/n you'll probably want something like Singular Solutions' A/D64x Audio Interface, which also gives you the full 8 ins/outs.

On the other hand, new CD players can be had for $79, so the DA conversion required for that level of s/n is pretty cheap. Maybe it's standard gear after all.

>will not work (I can't see any as the 68k is asynch and as long as I don't
>speed up the clock to elsewhere it should be ok).

Yes, it will work exactly as you expect, only a small (around 10%) speedup.
Why would you go to all that effort for a mere 10% speedup, though?

You could also consider replacing with a 12.5 MHz 68010 (I guess 16 MHz
parts never became available...). Then you could also get the benefit of the
loop-mode cache, along with the potential for virtual memory support.

>break?

Why don't you try it and see? }-)

On the ST a RESET instruction will cause a warm-boot.

4654. Gulam (MACROS / SOURCES) Question

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-02 08:51:04 UTC
From: jhh@cwi.nl
Message-ID: <8070@charon.cwi.nl>
Source record: 41653

Hello out there,

I've been using Gulam for years now, to the point that I'm hooked to it.
It's built-in micro-emacs editor is very nice too, but there is one thing
seriously lacking:

MACROS (more than one, that is)

I don't want to use another editor (not even other PD emacses/micro-emacses),
as it would have to be loaded every time I want to edit a file.
I seem to recall someone referring to the sources of Gulam a little while back
on the net. I, for one, would be very interested in those, so that I can try to
add a more general macro facility to the micro-emacs editor. Or maybe someone
else has already done this. Any information would be welcome (please send by
Email).

Roger-Hunen (rh0083b@medtronic.COM) wrote:
: Indeed, the SCSI exec core is very small (some 30 lines). However, there
: is a big pitfall. The DMA chip will only move data to/from main memory in
: 16-byte chunks. A MODE SENSE, for example, will return less than 16 bytes
: from many devices. You then need to request some extra bytes (INQUIRY is a
: fine command for that) without clearing the DMA FIFO first.

Actually, there is a trick to transfer single bytes over the DMA bus
in such situations. In most cases, however, having to send a second
command after the first one just to move DMA buffer contents isn't
so much a problem: Sector data always are a multiple of 16, and
even most diagnostic data comes in multiples of 16 bytes. In most
cases, only error handling is affected which is not required to
be fast as lightning, anyway.

>Does someone have facts on this point?

The blitter is used for IDE transfers only and you can disable the blitter
doing this by pressing the left Shift key while booting AHDI 6.0. (I think
it is the left.) In this case IDE data are handshaked by software, i.e. the
blitter is not involved.

A lot of other chips is initialised with the RESET instruction, e.g. MFP,
video chip etc. So the system is likely to break.

You cannot rely on registers D0-D2, A0-A2 and A5. The rest is
preserved. As far as I know, the docs actually say that only
D0-D2 and A0-A2 are touched.

The RESET instruction will reset _all_ peripheral chips, not just
the ACSI bus. Afterwards, you would have to re-initialize all
peripherals which is quite a lot of work 8-(8-).

There is no 100% safe way of resetting the ACSI bus, I'm afraid.
There is a procedure that works most of the time, though: Toggle
to FDC mode and back to HDC mode, read a byte or two from the
DMA bus (without waiting for ACKs), toggle back to FDC mode.

4661. ST overscan - a code

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-02 11:20:30 UTC
From: mapmh@gdr.bath.ac.uk
Message-ID: <1992Dec2.112030.4078@gdr.bath.ac.uk>
Source record: 41660
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Ok, well this is going to be the second posting of an overscan routine
and although most of the previous posting applies, this routine is
capable of a bit more.

For starters it is possible to extend the overscan even further to get
around 34 usable character display lines, this involves a second
critical switch between 50 and 60hz and then back again, near the top
of the screen.

Also, as it stands, this routine is pretty robust (I hope), it uses the
MFP timer B and there are 3 interupts during a screen scan, the first
happens near the top of the screen and does the switching business there,
the second happens about half way down the screen and here tell the
keyboard to shut up for a moment - this is to avoid annoying data loss
caused by the keyboard chip continuing to send data whilst interupts
are doing more important things. Also this middle interupt checks
that the 'scheme' of interupts are still in the same place, adjusting
if necessary. The third does the business at the bottom.

The checks to see when to do the switches read where the shifter is
currently reading from in memory and wait/go accordingly.

Note that you will need to allocate (I think) about 12032 extra bytes
of memory and as the routine stands you will also need to move the screen
physical address to a new (ie lower) location with this memory
available - I've left that up to you to do. You can do this 'legally',
wow! using the relevant bios routines if you use the code as it stands.

At it stands this routine has never hung on me, and I've tried silly
amounts of keyboard presses to try and mess it up without success. The
routine must be switched off if you access a disc though! I run it on
a 1MB STFM, but I haven't a clue if it works on the STE's, also I have
no idea what would happen if you used it in conjunction with a 60hz TV,
ie in the states - monitors should have no problem (I think).

To use it - you need to do the following:

call switit - this routine modifies the code slightly (oh dear what a
bad programming practice!) so that it will run in the
screen memory location given. I am not totally sure
that this routine will run with the screen address
anywhere, normally I put the screen on a 64k memory
boundary.
call startbig - This switches on the overscan routine
call killbig - this switches off the overscan routine

Note that if this routine does, for any reason, go wrong it will HANG
the machine, ie reset will be the only way out.

Feel free to email me with questions, queries, complaints, I'll try and
answer them if possible. Also let me know what machines it works on.

I have put some comments on the code - I hope they will help you to
understand what is going on.

Mark

According to Atari ST internals all the XBIOS and BIOS routines can affect
up to D0-D2 and A0-A2, so assume these are corrupted.

>any better suggestions?
Well, first: dont use line-A, its allways a bad thing. If you want to do it in
a window, the AES will supply you with the characters typed and intended for
that window, so you have to do all the parsing and displaying stuff yourself.
Output into the window is done by v_gtext(), but deleting a character has to
be done by vr_recfl() or something like that; you have to do the scrolling of
the window contents yourself. It will be a lot of code, in C I have written
a vt52 emulator, which is about 25KB in text, and I assume that there are
no solutions which are _much_ shorter, so good luck...

From: S.J.Harrison@newcastle.ac.uk
Message-ID: <ByMt23.8Jr@newcastle.ac.uk>
Source record: 41655

I have a similar problem with an Amstrad 1.44M floppy. I think the step rate is too high since the head usually stays still and the stepper motor buzzes, unless the step is one track only. It does work if you nudge the head in the right direction, though! (Not recomended...)

I haven't had time to play around with the step speeds, but I think that should cure it.

Simon.

>break?

I guess you're talking about what is called the RESET op-code in my 68k books. This pulls the 68k RESET line low for a while, then returns it to high again. The 68k processor itself is _not_ reset.

This has the effect of resetting all devices connected to the line -- i.e. all the important chips in the ST. This means that you'll have to reconfigure everything -- MPF, ACIAs, sound chip etc. etc.

In short, everything stops. It's a rather drastic method of interrupting DMA transfers, and likely to crash the machine if you try to do it in the middle of "normal" processing. I think there's another way of halting DMA transfers, but my DMA programming knowledge always was pretty sketchy...

Circuits like this have been done. You must slow the CPU to 8Mhz
when making any external accesses. Overall speed increase is about
10-20%.

4667. Re: VGA Monitor on 1040STf, take 2

Newsgroup: comp.sys.atari.st.tech

A standard VGA should be workable in mono. VGA have a fixed 70Hz vertical sync which will not work in color. Multisyncs will work in color and mono(not multiscan VGA).

Thanks George, now I'm convinced! HAM really does suck! Now I see
that it takes 32 bits of RAM to produce one 24 bit color. Not to mention
that only 25% of that 'pixel' (of the 420) will be the right color.

P.S. I belive you meant to say 1280 divided by _4_ is _3_20.

About two years ago the german magazine c't had a procect called A(tari) LI(nk)
A(dapter). The ALIA is connected to the DMA-Port and supports one to four
transputer-Links. Other DMA-Stuff may be connected in front of and behind the
ALIA.
Since I don't have the magazine around I cannot giver further refference at the
moment.

>
>Think about it for a while... it's quite clever.

I should think about it? Maybe you should consider that I
did think about it.

>Imagine an old ST program... it sets a colour to "777" (hex), expecting
>white. If the STe had made the 4th bit the most significant, then this
>would have been a middle grey - YUCK! However, by making the top bit the
>LEAST significant, "777" is just ever-so-slightly-darker than the brightest
>white, "FFF".

>So see, the bad computer is not the STe, it is the ST for using such
>an unthoughtful encoding. Remember the 8-bits? They ignored the least-
>significant bit for luminance... until the XL's finally came along and
>used that bit (I think).

The answer to this is simple. You define a separate screen mode
to support the extended colour definitions. Old programs would
all work normally. Programs supporting the new colour set would
have separate colour palettes. Consider that most proograms that
use colours at all are well over 64K you might add about 100 bytes
to the program startup for the extra code to detect the new colour
range and swap in the palette. It would have been better solution
for those of us who write programs that use the luminence information.

And yes, it would have been better if Atari has had "planned
ahead" and simply started with the coding shifted over in anticipation
of newer hardware. And of course it would have been nice if Atari
had planned ahead and not used the 16 bit block interleave screen
format. And it would have been nice if Atari had used an expandable
rule based screen format definition system. And it would have
been nice if the graphics kernel had been been designed for use
with higher definition screens. And it would have been nice if
the original OS had been written in processor independent code.
And I suppose there are lots more that would have been nice. But

again, all this comes under "planning ahead." And that's what I'm
doing now, by seeing how much "planning ahead" Atari did this time.
:-)

>The correct way to specify colour on the ST would have been with a

>
> xxxxxxxx HMLxxxxx HMLxxxxx HMLxxxxx
>
> H=highest, M=medium, L=lowest
>
>Then, everyone would probably have complained anyway about how
>"0xE0E0E0" was white rather than simply "0x777"....

I wouldn't have complained. In fact, I can't think of anybody
I know who would have complained. Furthermore, if the extra bits
have no effect, you could define "white" as 0xFFFFFF. It just
won't display any differently from 0xe0e0e0. No problem. Might
even be useful.

>Note however, that the VDI uses a 30-bit colour encoding (0 to 1023 for
>each of R, G, B).... that should never go out of style... until the human
>eye evolves a bit more.

Actually, I understand that Silcon Graphics is up to 48 bits,
but no, I don't expect I'll ever really need that level of capability.
I might *buy* it some day, but I won't *need* it.

Okay, it seems I've missed something. I thought it would be enough to take the original signal from the TV, CD or whatever and use it as input to the Falcon and to the normal hi-fi equipment. Then let the DSP decode the signal and return the center and the surround on the outputs on Falcon (or does it use the same plugs for in and output?). This way you would have all the signals needed; but I do make the assumption that the original signal can be used un-modified (I know I can play a normal music CD recorded with dolby surround without additional hardware, but then I don't get anything but the normal stereo sound).

Also I thought that Dolby surround was what seems to be Dolby Surround Pro-Logic (who's inventing those terms :-?). I dare not think of what Spectral Recording is (unless it is just another way of saying the same thing?)

Anyway, I'm hooked after a little demonstration of the new Bang & Olufsen video-system (although I don't like the pricetag: 100.000 DKr, where 1$ appr. 6 DKr).

4673. Memory distribution on the DSP

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-02 15:52:31 UTC
From: morgado@vxdesy.desy.de
Message-ID: <Byn2rK.2vt@dscomsa.desy.de>
Source record: 41664

Does anyone know how the 32kwords of DSP memory is devided into the DSP's three memory
spaces (X, Y and P). From photographs of the inside of the Falcon, it looks as though there are
three memory chips, each eight bits wide making up the 32k of 24bit words. This probably
means that it is only P (program) memory which is extended off the internal memory space. If
this is the case it becomes another serious shortcoming in the Falcon design. Lack of X and Y memory off-chip will require most digital filtering applications to run in on-chip memory,
restricting the amount of data that can be processed in one filter pass.

I've tried a 68010 in my ST with both TOS 1.0 and 1.4 with no success.
The interrupt stack frames are not compatable. I used to send a lot
of email to Atari people on Compuserve, and GEnie trying to get Atari
to switch to the 68010 for loop mode and the improvements in integer
math routines. I do not have 2.0x so I can not report on that, except
that there is a "cookie" to identify which processor is in the system.

4676. GCC 2.1.2 linker errors

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-02 18:07:31 UTC
From: cmh@eng.cam.ac.uk
Message-ID: <1992Dec2.180731.16981@eng.cam.ac.uk>
Source record: 41671

I am still failing to get GCC running on my 1040STF. I have read as much documentation as I can find - if there's some essential reading, please point me to it :-)

I have got to the stage where everything is OK until the linker tries to link more than a couple of object files. In an effort to begin learning C, I have written a small mandelbrot generator which I compile with the following command line...

```
gcc mandel.c -o mandel.ttp cplx.o graphic.o -lpml -v
```

mandel.c #includes graphic.h and cplx.h, these being two very simple libraries I have written for handling complex numbers and simple graphics (no surprises there!)

Everything is fine until the linker gives the message:

```
mandel.o: undefined symbol ___ltdf2 referenced from text
```

I have programs that I can successfully link and run with either of cplx.o or graphic.o, but anything I try to link with both together falls over, as above.

I would be very grateful if anybody has any ideas as to what is the problem. In which .olb file should ltdf2 be defined, as I've never seen it before ?

System configuration is: 1040STF
4 Meg RAM
SM124
48Meg SCSI HD
TOS 1.2
Gulam

Thanks in advance, and sorry this post is so long...

Christopher Hicks

Source record: 41674

Hello,

I posted this once before, but with no responses. Can some kind [German]
please find out some information about the Graphics Cards produced by
"Matrix Datensystems" for the Atari ST. I beleive that they make a large
number of different cards, and from some magazines I gather that at least
2 of thier cards [the C128 and C32] are designed for a regular old ST.

I would like to know if they take orders from the US, and do they have
some sort of brochure describing what cards they offer. I am looking for
resolution on the order of 1280x1024, but I am not interested in a large
pallete as monochrome will do fine on my system.

P.S. If someone could find out if "Matrix Datensystems" has someone who
speaks english, Then I would call them and talk directly. All I need
is a phone number.

Many Thanks,
scott@dmi.stevens-tech.edu

Now we're leaving the realm of comp.sys.atari.st and moving into rec.audio...
In consumer audio, there is just a single Dolby surround encoding method. There are two levels of decoding though, "Dolby Surround" and "Dolby Pro-Logic." In both cases, a monophonic surround channel is extracted as the difference between the Left and Right channels, and sent to the rear. In Pro-Logic, you also get a center channel which is extracted as the sum of the Left and Right channels. Of course, "sum" and "difference" is an over-simplification, in the case of Pro-Logic.

In plain Dolby Surround, the main speakers (front left and front right) still send out all the original information from the stereo signal, including the encoded surround channel. The rear speakers send out mainly the surround info, but some Left or Right noise can creep in as well.

In Pro-Logic, the isolation between channels is much tighter; only signals that are exactly 180 degrees out of phase (between left and right channel) will go to the rear channel, and only signals that are exactly in phase will go to the center channel, and these signals will be removed from the Left and Right speaker outputs. Pro-Logic pretty much demands DSP, regular Dolby Surround can be "decoded" just by tying the two positive speaker leads (from left and right) into a third speaker.

I'm not really sure about Spectral Recording, but I know it sounds pretty good on my Dolby Pro-Logic system. I'd guess it's a similar setup that just isn't licensed from Dolby Labs.

As well as agreeing that I've yet to see a 24 bit recorder in a
studio, I'd like to point out that "cd quality" is a rather nebulous
term, as what is "cd quality" as a standard. Is it a top of the line cd
player with seperate outboard dac, costing N * $1000, or is it the sub
$200.00 portable, or somewhere in between? I have a older Teac portable
cd player that was only a 14bit dac, and it sounded pretty good, IMO,
and I doubt the electronics in it would be much better than what's in
the Falcon.

You can shove more memory above the 4Meg limit without worrying about the evil bus error. I have implemented a general purpose expansion bus out of my 1985 1040ST (almost 12 Mbyte address space with DTACK). They made it easy for us by using open collector (or open drain) logic on the DTACK signal going into the 68K. This allows you to short DTACK to ground with another open collector driver when your device that you stick above 4Meg is ready to drive data or has accepted it. The magic bus error state machine (in the MMU I think) actually watches the UDS LDS and maybe the AS lines and then begins to start counting cycles. If it sees DTACK then it stays quite and just resets. If it does not see DTACK, it gets pissed off and generates a bus error. This is a really cool feature for folks like me who are developing custom stuff to connect up the the ST. If I screw up, the machine does not hang it just gets a bus error.

A clever person would just program up some PALs and add some counters to refresh a hunk of DRAM above 4Meg. This PAL would generate DTACK for an open collector driver (74F06) shorted directly to the DTACK pin of the 68K. The only pisser is that you can't tell the ST OS that you would like this new RAM to be video RAM. The MMU can't address it.

If you want the schematic and PAL code of the expansion bus (it is buffered to help protect you from death) send me a letter and I'll send a photo copy of it. You can make it for under 10 dollars. You can blow off the PAL if you want and just use TTL gates for the decoder if you can't get to a PAL programmer.

Send it to my house :

>If you mean a PC-minitower: Mega motherboards do *not* fit in this kind of
>mini-towers -- it's even a pain to stuff them in big towers. And then...
>all the re-wiring, (expensive) cables, floppy&HD placement... Yack...

That's the truth; a Mega board is about 1 foot square. Most tower cases look plenty big on the outside, but internally a lot of space is hogged up by the disk drive bays. Mine barely fits into my full-size tower case, there isn't a hope of getting it into a mini-tower and still using the disk drive mounts.

(I.e., I found that the case had enough width and depth, but very few of them give you anywhere near 1 foot of height, taking the drive space into account.)

Another slight problem is that the mounting holes are nowhere near lined up between board and case, so you probably have to drill new mounting holes in the case. Finally, it is a real drag routing cables thru the rear of the case into the board; extension cables are a good idea for the printer and modem ports so you never have to swap 'em from the ST end.

Oh yeah, if you've got the (square) board oriented so that most of the connectors face the back of the case, your ROM port and keyboard cable jack will be on the bottom. I had to bend my ROM connector 90 degrees (parallel to the bottom) so I could still plug in my cartridge-port RAMdisk. Btw, the Mega just uses 6-line RJ-14 (telephone-style) cable for the keyboard, not that 7-pin inline header that other STs use.

The true-colour mode will actually be FASTER for some applications.
All wire-frame graphics will be faster with the true-colour mode (but
of course, how many colours can you need for wire-frame!). Some types
of sprites are faster, etc. But mainly, I see it useful for non real-time
games and CAD/3d-rendering programs, all of which could use the HAM mode,
but would be much more complex [ie. unlikely to be written, given equal
developer support] than the same application in True Colour mode.

4686. Anyone try Hardware Overscan?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-02 23:18:35 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1992Dec2.231835.24829@oz.plymouth.edu>
Source record: 41679

Hello,

I recently retrieved OVERSCN3.ARC from A.A. It sounds very cool,
but it was also out of Europe, and if I remember, did not mention the
1040 specifically.
Has anyone with a 1040STf (or at least a 1040ST) tried this
modification? I would like to hear from anyone that has before I do it
myself. For example to do you follow the 520 or the Mega directions?

Thanks,

Stephan

;
I bet that 90% of programs for the True Colour modes will be demos, and 80% of
those will be Mandelbrots created using the DSP (and another 15% fireworks
displays). As you imply above, the lack of planes makes this mode ideal for
plotting 1 randomly coloured pixel at a time. The DSP should be great for
calculating Mandelbrots because they require alot of calculation on a very
small amount of data.

A standard VGA monitor has a fixed 31.5 KHz scan rate. That will be unusable on the ST, which uses 15.75 khz for color and 35 khz for monochrome. You need a multiscan monitor that can operate at any frequency from 15-35khz with refresh rates from 50 to 70 hz. You have to check the specs pretty carefully on any multiscan monitor you're thinking about; many current monitors won't scan as slow as 15 khz, many also won't handle the 70 hz monochrome frame rate.

Could somebody explain to me why 24-bit CD players will ever be available?
The BBC use a 12 bit digital line between FM transmitters and the quality is
very good with the unavoidable has modulation hiss added in. A cheap CD player
(probably accurate to 14 or 15 bits) is noticably, but not considerably better
at normal listening volumes. The difference between a cheap and expensive CD
player is indestinguishable at normal listening volumes, and barely detectable
at any volume. So what is another 8 bits going to do?
The new systems being marketed at the moment (mini-disc and DCC) have a lower
S/N ratio than todays CDs, so there is obviously no demand for better quality
either.

There have been pictures of the insides of the Falcon - has anybody looked up the specs of the CODEC chips, or have an opinion about how much interferance is likely from the rest of the board given the layout? Even better, has somebody tested the Falcon and got a S/N ratio?

I did this on my Mega. I would bet that you use the 520 instructions on your 1040, since the 520/1040 layouts are so similar. (Could even be identical depending on board revision number...) Neither of them are similar to the Mega.

>in the 8bit VGA modes.

Better believe it. The Atari Falcon 030 has a 16 bit data bus (this means
that the memory, custom chips, and the expansion ports are only 16 bit.
It also has only 24 bit adressing. This doesn't really make the falcon a
"fully 32 bit computer" like Atari advertised. The only 32 bit chips in the
falcon are the MC68030 and MC56001. All of this wouldn't make the Falcon
all that fast and on top of this, the Falcon uses a shared bus technology
which means if your program uses sound and number crunching and graphics
extensivelly the performance will decrease dramatically. Not to mention
what would happen if you dare and multitask!

Now take A1200 for example. IT is not so feature packed as the Falcon (even
though it can be expanded to match (and beat) the falcon) but it IS a fully
32 bit computer with separate busses for custom chips and processor (it also
has 24 bit adressing though which only affects the amount of memory you can
have anyway (max of 14 Mb)). Even though A1200 uses a slower processor (14.14
MHz MC68EC020) the performance is MUCH better than the Falcon's due to it's
architecture.

I know this doesn't really relate to your message.
I am not a die hard Amiga fan but I do think that Amiga is the best computer the money
these days. (I wouldn't mind an Alpha DECStation though)
I also think that Atari fans have gotten to enthusiastic about the Falcon and
have made it out to be the best computer in the world so I wanted to point
out a few of Falcon's not soo good features, which are, euphemistically, very
crippleing. Sorry about the super long sentence.

Greetings.

I'm only an Economics/Civil Engineering student and probably haven't had as
much access to CAD programs than you, but I haven't seen any true-colour CAD
programs. Most of them have a few colours for the icons, and plot the display
in monochrome (green on black, orange on black). Some of the electronics
cad programs may use up to 32 colours (5 bit planes) but using 16bit (or is
18bit) true colour mode seems way over the top.
(I only have access to PC's - IBM clones and Macs, so CAD programs using 32k
colours may exists on the Sparcs, Suns and DECstations floating around).

If you were talking about rendering ray traced pictures, then the more colours
the better, but HAM8 would be perfectly acceptable for this and might do a
better job than "true colour" mode on the falcon.

What's the display limitations of "true colour" mode, 320x200 or 1280x400?
Just curious.. (I've forgotten now)...

Regards,

Jim Fang.

Please, we've already been through all of this quite a few times before.
The memory subsystem is 32 bits wide, and uses nybble mode DRAMs. The video
hardware gets full 32 bit access to this memory. The CPU gets only 16 bit
access to the memory. The 56001 is not a 32 bit chip. It is, depending on
your point of view, a 24, 48 or 56 bit chip, but does not have any 32 bit data
types.

If you aren't sure of your information then you shouldn't be posting it in
the guise of factual data. (Of course you could be dead certain and still be
dead wrong, as so many posts in this thread have been...) If you haven't used
a Falcon then you have no basis for judging how it will perform in any
context.

At this point there's nothing to be gained by further discussion of the topic.
Perhaps it's time for a regular Falcon specs posting, at least for the next
couple of months. Anything to to stop all this endless question and speculation
that's been going on...

Since you are apparently gone from Atari and reading this group sometimes
and are hopefully a bit freer to speak about things, I have one question
for you that I always wanted to get answered:

What the .... was done at Atari in between 1986 and 1990 in terms of
software development ? The few TOS changes from 1.0 to 1.6 (TT inclusively)
should have taken about 6 man months at most. (*)

Was there an endless party in Sunnyvale, till the cash flow from Europe
trickled off ?

Nat!
(*) I'd say 2 months would have been plenty. (har)

I can only take that as sarcasm (civil engineers see more CAD packages then
us CS types :-])

Most CAD packages include rendering. For shading and colour-coding of
components, etc. True colour makes life so much easier (no allocating
of colours to worry about). Even the somewhat lowly CAD3D 2.0 (Antic
software?) had a rendering/solid modelling screen.

>What's the display limitations of "true colour" mode, 320x200 or 1280x400?
>Just curious.. (I've forgotten now)...

320x480 in VGA mode. You can get 640x400 on a 200-line atari monitor, but of
course, that is interlaced. I'm still wondering if 640x480 is possible on a
higher-qualiity multi-sync.

Actually 640x480 on the SC1224 and on TVs. The only 400 line mode on the Falcon is the ST High-Rez compatibility mode. With overscan 768x480. With even more overscan, 768x512. With a decent multiscan monitor, you can get an 800x600 display, but not in true-color. (640x480 true-color would be almost 37 MB/sec at 60hz. The CPU would be reduced to 1/3 its original performance in such a mode, which is probably why the OS doesn't allow it. You can probably get there by tweaking the video controller registers yourself...)

4697. Wangtek 5150ES problem solved!

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-03 09:57:15 UTC
From: rh0083b@medtronic.COM
Message-ID: <1992Dec3.095715.11257@medtron.medtronic.com>
Source record: 41607

A couple of weeks ago I reported in this newsgroup that I had a problem to get a Wangtek 5150ES tape drive working with my ST. This problem has been solved. If you are interested in what was wrong and in how it was fixed, read on. If not, hit the N key.

Problem Description

I purchased a new Wangtek 5150ES tape drive and hooked it up to my ST. Using the TAPEBIOS or MT software I could write to tape (which was verified on a SUN Sparc), I could read the drive status but I could not read from tape. Any attempt to read data locked up the SCSI bus. Apparently no data was transfered by the read (only later I found out that some data occasionally made it). Eventually the software timed out with the SCSI bus still busy (hard drive could not be accessed). Only a system reset would clear the SCSI bus.

System Configuration

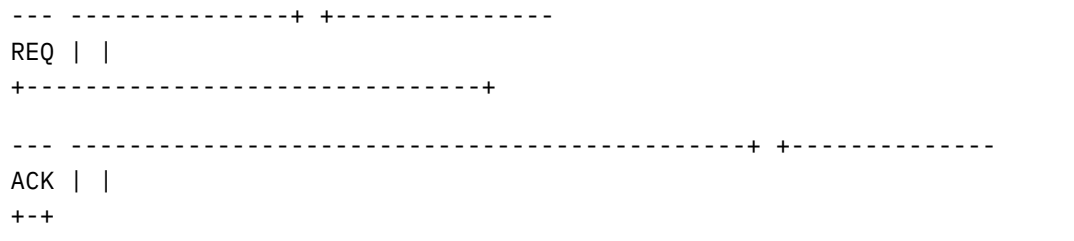
Computer : Atari ST 1040 with 4 MB RAM upgrade
Adapter : ICD Advantage Plus ST
Hard drive : 105 MB Quantum Prodrive
Tape drive : Wangtek 5150ES
Software : TOS 1.4, TAPEBIOS 1.5 (or MT)

Software Redesign

At first I suspected a software problem (MODE SELECT did not work too). I acquired copies of the SCSI specification (draft 17B for X3.131-1986) and the 5150ES OEM manual. With that information I designed a brand new driver which worked for all commands... except READ. Reads would still hang.

Hardware Analysis

I now suspected a hardware problem. I conjectured that the 5150ES might provide data too fast for the ST. I hooked up a logic analyzer and was stupified to find that it was the tape drive that gave up, not the ST! After a few bytes the tape drive no longer asserted REQ to transfer the next byte. Sometimes at least 16 bytes were transfered which were then delivered to the data buffer by the ST's DMA chip. The REQ and ACK signals on the SCSI bus looked as follows.



The ACK pulse was only 60-70 nsec wide and was asserted about 700 nsec after assertion of REQ. Apparently the ICD host adapter only asserts ACK when the data has been transfered to the ST in order to meet the data hold time requirements of the DMA chip.

The tape drive negated REQ as soon as ACK was asserted and in turn the host adapter negated ACK immediately. After a few bytes the tape drive missed an ACK and deadlocked the transfer.

The SCSI spec does not state minimum timing requirements for REQ/ACK cycles in asynchronous transfers. Though one may argue that 60-70 nsec ACKs are really short, it must be concluded that the ICD host adapter does not violate SCSI REQ/ACK timing requirements. Therefore the tape drive is to blame for missing the ACK.

Solution

I modified the ICD host adapter to insert a delay in the REQ line (pin 48 on a single-ended SCSI bus). For that purpose I used the 6 gates of a 74LS14 (hex inverters with Schmitt trigger inputs). 4 gates are probably enough, and even 2 may do the trick. As a result REQ/ACK timing is much more relaxed. The tape drive works fine now. Hard drive performance is only slightly degraded.

Epilogue

I will develop my tape software to completion and then post it to comp.{sources|binaries}.atari.st probably early January. The software will be in the public domain.

Acknowledgements

I thank the people on the net for providing me with valuable information on SCSI, SCSI software and Wangtek 5150ES tape drives. I also thank the Dutch and local Wangtek distributors for providing me with the OEM info.

Regards,
-Roger

Basically agree, but see below...

>>"Professional recording" means the kind of recording used by professionals.
>>For the most part, that would be 1" analog, 2" analog, a very tiny number
>>of 24-bit recorders, and a whole lotta 16-bit digital machines. I wonder if
>>Prince, at his (analog recording + 16-bit mastering) Paisley Park studio,
>>realizes that he's not a professional? He should've asked George!

Recording engineers are beginning to feel that 18-bit A to D conversion, 24-bit
processing, and 20-bit recording DOES sound better than 16-bit.

>>Until there are a few thousand 24-bit CD players out there (current count:
>>zero), 16-bit digital is all pros need. Don't listen to this weenie; he's
>>lying to you.

Wrong, that it is necessarily all they need, but right that it is all most of
them use :-)

>Could somebody explain to me why 24-bit CD players will ever be available?
>The BBC use a 12 bit digital line between FM transmitters and the quality is
>very good with the unavoidable has modulation hiss added in. A cheap CD player

The 12-bit scheme used by the BBC uses non-linear coding to achieve 80dB S/N.
This is digitally processed to 16-bit linear coding before being passed to
the D to A convertors

>at any volume. So what is another 8 bits going to do?

The extra 8-bits give higher resolution (read lower distortion) at low
recording levels, and lead to higher precision in any digital processing.
Rounding errors in 16-bit math ARE audible as S/N degradation.

>>> The broschure makes the interesting claim of "better than CD" sound.
>>> Maybe this referes to the 50 KHz sample rate, but it's not clear whether
>>> Atari has managed to implement a "CD quality" signal/noise ratio in their
>>> Analog interface. They're due some kudos if they have.

>>
>>With the standard $799 machine, highly doubtful; most people don't need
>>that. For studio-quality s/n you'll probably want something like Singular
>>Solutions' A/D64x Audio Interface, which also gives you the full 8 ins/outs.
>>
>>On the other hand, new CD players can be had for $79, so the DA conversion
>>required for that level of s/n is pretty cheap. Maybe it's standard gear
>>after all.

I would *guess* 80dB S/N for the DAC, and 70dB for the ADC. This is pretty good, but not 'professional', and not really CD quality.

Spectral Recording (SR for short) is an analogue noise reduction system used
on professional multi-track analogue tape, and has nothing to do (directly)
with surround sound.

I've noticed an interesting problem with SerialFix (1.1 I think - whichever one claims to be the 'final be-all and end-all solution'...

On my TT, it redirects _all_ serial output to Modem 1.

Input is fine on the other ports.

Without it, all works fine & dandy. (I don't think the TT has ever tried to handshake 8)

I've also experienced weird problems with the TT's serial ports freezing up - I have a sad feeling that this is related to my AJAX problems, and that I may have a sick motherboard.

sigh

>filtering applications to run in on-chip memory,
>restricting the amount of data that can be processed in one filter pass.

I feel I must stamp on this before it gets out of hand :-) I believe that
it is basically as Carlos says, BUT WITH A VERY IMPORTANT EXTENSION. The
bottom 16k of P memory is reflected as X, and the top 16k of P is reflected as
Y.

Thus, we have two 16k by 24-bit sections of memory (call them A and B). Now
A can be accessed as P(0 to 16k) or X(0 to 16k), and B can be accessed as
P(16 to 32k) or Y(0 to 16k).

There is a more or less simple way: Create a dialog of Strings, a change the coordinates to the window-coordinates. The updating means simply call objc_draw with the rectangle to be redrawn.

Of course some work is left to you: create and open the window, load the resource, do redraws and change the dialogcoords, if windows are moved or sized. So it isn't as easy, as itt could be, but graphically surfaces are not easy to be programmed...

Source record: 41604

Hello!

I am contemplating the purchase of an ICD Link, which is a SCSI adapter for the ST that sits in the DMA plug of a DMA/ACSI <-> SCSI cable. The adapter draws the power it needs to operate from the termination power of the SCSI device that it's plugged into.

I have heard that some (mostly older) devices provide no or only insufficient term power, and thus won't work with the ICD Link.

Does anyone have a list of such devices, or general experience with the Link?

Thanks -- Volker

Howard has said it all.

Now to muddy up the memory waters a little more...
The memory is DUAL-PORTED between the video and the rest of the system.
The 68030 shares the bus with the DMA devices.

>If anyone has C or BASIC code to convert postscript to ascii can they send
>it to me?

What do you expect such a program to do? Suppose you feed it a PostScript program describing a mixture of charaters in various sizes and some graphics, what should it produce? How general would you like it to be? Keep in mind that in general such a program would have to include a complete PostScript interpreter, which is not really a trivial thing to write.

Glen, in terms of "real-world" graphics HAM provides a good
level of information retention in a fast-accessed, compact data form.
This type of idea (compromising full information retention for
data space saving) is the "big news" stuff in the higher levels
of the graphics industry. It's the philosophy at the heart of
JPEG and FIF formats. If you study graphics traditional graphics
technology, you'll find that hard edge black to white transitions
only occur in the virtual reality world. If you read technical
analysis of photographic materials and equipment you'll find that
"resolution" is properly compared only where the "contrast" threshold
is defined. In other words, if somebody is stupid enough to brag
to me that he has a 200mm telephoto lens for his Nikon that will
pull 100 lines resolution, the first thing I'll ask back is "at
what contrast level?" (The second thing will be at what spectrum
range, but that's getting really techy. :-) Television equipment
is no different in this respect. The bottom line is that for
displaying photographs a HAM-like system with the same palette
range as a "true colour system" and with the same number of pixels
will display *completely* indistinguishably, (viewing whole pictures)
probably 50% of the time and "almost indistinguishably" 80% - 90% of
the time. The old HAM mode was good enough that back in the
days of the introduction of the Amiga, most lay people felt that
the Amiga had "photographic" quality. If you weren't around,
you should ask people who were. Apparently the new HAM is substantially
better.

Now let's get down to some "real world" criticisms. The *real*
drawback of HAM is that it requires calculations. In terms of
page flipping animation, that's not bad. But in terms of tools
and programming it's a bad hit. If you try Deluxe Paint IV on a
HAM mode with a standard 8 MHz 68000, that's bad. It might be
passable on a 25 MHz '040 rig, but that's something I'll have to

have some time to use before I make up my mind. I expect that a good paint program would be about as fast on the Falcon as on my 1040ST.

Ideally, the "computer of tomorrow" will have both hardware based HAM or similarly compressed data formats and "true colour" modes for speed of work. Neither is perfect.

Incidentally, since the whole discussion seemed to have started regarding the 16 bit v. 32 bit data bus, I may have missed a significant posting, but I've seen no real definitive information saying that the 32 bit bus on the Amiga is necessarily faster. The Amiga Zorro II bus is multiplexed, and it's not necessarily any faster than a 16 bit bus, if the 16 bit bus can pull 2 cycles to 1. There's much more to this than meets the eye.

So far, from what I've read, the Atari has, once again designed the better sound machine and the Amiga has brought out the better graphics machine. But one of the *real* questions is whether Atari will get a good OS in time? From what I've read about MultiTOS, it's a wasted effort. They should have skipped the idea and just gone with OS-9.

There is no officially documented way to pass register or stack parameters
to a function called by Supexec().
To remain on the "legal" side, you'll have to use global variables for
paramter passing.

It won't, but the machine is very likely to crash immediately after the RESET instruction, thus causing a reset.

The correct way is to jump to _syshdr->os_start.

4717. Re: Falcon DSP sounds

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-03 19:50:13 UTC
From: rossin@hpfcso.FC.HP.COM
Message-ID: <107480002@hpfcso.FC.HP.COM>
Source record: 41617

I've connected a TMS320C30 DSP (33 MFLOPs of balls) to my 1040ST. The DSP board that I made has a host access port (code development from the ST), MIDI in and out, and a CS4216 CODEC (16-bit A/D and 16-bit D/A in stereo). The code that I wrote for the DSP interpretes the MIDI commands and makes tones.

The tones are made using a techinque I stole from a paper written in 1973 about frequency modulation. Basically the code implements the following equation:

f=A(t)*cos(p*t + I(t)*cos(p*t*M) + O)

The constant p sets the pitch of the fundamental tone that your ear may hear. The function A(t) implements the Attack, Decay, Sustain envolope of the volume. The funciton I(t) implements the Attack, Decay, Sustain envolope of the harshness of the voice. When I(t) is zero, the voice sounds very smooth becuase the equation basically becomes a cosine wave. When I(t) becomes nonzero cool shit happens. The bigger I(t) is, the more harmonics there are in the output waveform. This is the difference between a pipe organ sound and a raspy car horn. The constant M gives another level of control over the sound. If M is 1/3, 1, 3/2, 2, etc the harmonics will be placed at pleasnt places from the fundamental frequency. If you set M to 1.1345 then you will get a very harsh sound as the harmonics will not be placed at very regular intervals. Read about Fourier Analysis for more details (it hurts my head). The last thing is the constant O which when set to zero has no effect. When set to a nonzero value will make a fluctuation in the output (a cool effect).

The big deal here is that when these dudes wrote the paper they had a PDP-11 do the calculations and store the results in RAM. After it finished, it would send them to an 8-bit DAC. Today you can do it in real time and control the parameters with MIDI! My implementation allows me to implement 6 voices in real time. The cosine table is done with a 2K element table. It sounds real good. Bells are amazingly perfect. By wiggling just a few parameters very different sounds can be made.

I'm sorry if this sounds like an AD but the current generation of signal processors that are available are just amazing. I'm very pleased that ATARI put a DSP in the FALCON with some balls. Even though it is a fixed point part you can still do amazing things if you are carefull (my C30 is a floating point DSP so I'll stick with it). Enjoy the land of DSP but be prepared to read a great deal of "boring" papers filled with really flipped out math. Once you get past the math that proves the algorithm you can find some really amazing tricks that just need a few adds mults and the like. Make sure that people are tuned into Motorola. If they are anything like TI they will have boat loads of material (code and application notes) that they will hand out for free or really cheap.

Later

Ted Rossin the butt hole not incorporated

4718. TOS 2.06 Physical Address

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-03 20:22:23 UTC
From: rossin@hpfcso.FC.HP.COM
Message-ID: <107480003@hpfcso.FC.HP.COM>
Source record: 41616

Can someone give me a clue on why TOS 2.06 has to have a monster called the TEC. I don't want this thing in my 1985 ST but I do want TOS 2.06.

I want to make my own adapter that is placed where I have room in my ST. I may even put it outside my ST on an external bus that I made that addresses the space between the 4 Megs of RAM and the cartridge port. It generates it's own dtacks so decode and DTACK are no big deal.

I don't have any room near the 68K becuase of my ST bus generator. I also don't think TOS 2.06 is worth 140 bucks. From what I have seen on notes so far, the big deal is that TOS 2.06 wants to live in the address range 0xE00000->0xE3FFFF. This is different from 0xFC0000 to what ever on the 1040ST. Also, the 1 Meg bit EPROMs are physically and electrically different. Can anyone confirm that TOS 2.06 does really start at 0xE00000? This should be cake to do. Just do a 32-bit read at address 4. If the number looks like 0x00E0???? then the ROMs are telling the 68K to jump to some address in the 0xE00000 space. Address 4 is the reset handler jump address. This address and location 4 (0->7 in byte address land) should be the same as the first 8 locations in EPROM space since that are remapped.

If it is indeed the case that OS should start at 0xE00000 I am planning on doing the following.

1. Make a very simple, very cheap board for my external bus that maps the two EPROMs into the 0xE00000->0xE3FFFF space that generates dtack. I've done this before for an ERPOM disk emulator so no sweat.

2. Keep my TOS 1.0 in their current happy home (under the ST power supply).

3. Let my ST boot TOS 1.0 as usual.

4. Run a tiny program that:
a. Gets into supervisor state (thanks ATARI for that evil OS call)
b. Disables all interrupts (write to status regiser)
c. Does a 32-bit read at location 0xE00004 to get the reset hander address.
d. jumps to that address.

5. At this point I predict that my ST will boot TOS 2.06

If anybody sees a problem with this let me know. I'm a hardware hacker with a logic analyzer in my pocket so I can trace the boot process from the TOS 2.06 ROMs but I would rather know any gotchas in advance if I could.

Thanks in advance for any help. The big help I need is the 32-bit value at location 4.

Bye

Ted Rossin

Looks like it's time for a re-post of the Falcon graphics capabilities. This is from John Townsend at Atari (on Genie I believe) :

Resolutions available on the Atari Falcon030
(c) 1992 Atari Corp. Written by John Townsend
==
This document may be re-printed again and again as long as the Atari
copyright remains intact.
==

A couple of notes: Unlike previous machines, there are just too many resolutions to give each resolution a name. Therefore, I will do my best to describe what the resolution is and which monitor it is on.

- NOTE: TV and a Color Monitor are the same.. by Color Monitor, I am talking about the standard SC1224. By VGA, I mean a standard VGA Monitor.

40 column modes ("column" means the number of x pixels divided by 8)
----
4 color, normal, TV: 320x200, 4 colors, 2 planes
16 color, normal, TV: 320x200, 16 colors, 4 planes
256 color, normal, TV: 320x200, 256 colors, 8 planes
True color, normal, TV: 320x200, true color
4 color, interlace, TV: 320x400, 4 colors, 2 planes
16 color, interlace, TV: 320x400, 16 colors, 4 planes
256 color, interlace, TV: 320x400, 256 colors, 8 planes
True color, interlace, TV: 320x400, true color

4 color, normal, VGA: 320x480, 4 colors, 2 planes
16 color, normal, VGA: 320x480, 16 colors, 4 planes
256 color, normal, VGA: 320x480, 256 colors, 8 planes
True color, normal, VGA: 320x480, true color
4 color, line-doubling, VGA: 320x240, 4 colors, 2 planes
16 color, line-doubling, VGA: 320x240, 16 colors, 4 planes
256 color, line-doubling, VGA: 320x240, 256 colors, 8 planes
True color, line-doubling, VGA: 320x240, true color

80 column modes
----

2 color, normal, TV: 640x200, 2 colors, 1 plane
4 color, normal, TV: 640x200, 4 colors, 2 planes
16 color, normal, TV: 640x200, 16 colors, 4 planes
256 color, normal, TV: 640x200, 256 colors, 8 planes
True color, normal, TV: 640x200, true color
4 color, interlace, TV: 640x400, 4 colors, 2 planes
16 color, interlace, TV: 640x400, 16 colors, 4 planes
256 color, interlace, TV: 640x400, 256 colors, 8 planes
True color, interlace, TV: 640x400, true color

2 color, normal, VGA: 640x480, 2 colors, 1 plane
4 color, normal, VGA: 640x480, 4 colors, 2 planes
16 color, normal, VGA: 640x480, 16 colors, 4 planes
256 color, normal, VGA: 640x480, 256 colors, 8 planes
4 color, line-doubling, VGA: 640x240, 4 colors, 2 planes
16 color, line-doubling, VGA: 640x240, 16 colors, 4 planes
256 color, line-doubling, VGA: 640x240, 256 colors, 8 planes

and lastly.. there are compability modes for ST Low, ST Medium, and ST High on both VGA monitors and SC1224 monitors. (On a color monitor, ST High is achieved by using the interlace mode).

Also, the ST Monochrome monitor (the SM124) will work with Falcon030 as well. However, it only supports one resolution: ST High Resolution.

All modes on a TV can be overscanned. This means multiplying the X and Y resolution by 1.2. For example, modes with 320 pixels of horizontal resolution (X res) will become 384 pixels across, and modes with 640 pixels will become 768 across. Overscanning is done in the X and Y resolution. You can't do them independently. Special Note: On a VGA monitor, overscan is "faked".. since the video hardware doesn't have the capability to do overscan on a VGA monitor, we made it so that if a overscan mode is set on a VGA monitor, you still see the normal size screen, but the screen is a window onto the bigger overscanned image. Make sense? We did this for compatibility. This way if a game that has an overscanned starup picture can use the same pic on both the VGA monitor and the TV monitor. Pretty cool, eh? <grin>

BTW.. Overscan can NOT be set from the desktop. The AES and Desktop will work just fine with it, but because you can't see the parts of the screen, we thought that that option shouldn't be available from the desktop. We don't want to confuse people. However, Overscan can be set using a new XBIOS call (Vsetmode()).. so it is still available.

I hope I haven't made any mistakes. I triple-checked this document in search of errors and I couldn't find any. If you do find some, send me Email on GEnie (to TOWNS) or CIS (70007,1135) and let me know.

-- John Townsend, Atari Corp.

PS. Anyone would would like to reprint this message, please do so!
The smaller the number of times I have to type that message, the
more my fingers with thank you! ;-)

After looking at this one more time.. one point to clear up: By
saying SC1224 Color Monitor, I mean any Color Monitor that Atari
have manufactured for the ST/Mega/STE/MegaSTE computers. Clear
as mud? ;-)

Now, everyone type "s" and save a copy of this message ok, then maybe there
will be no further questions (yeah right :-).

Cheers,

You can use the new TOS 2.06 with your STE. Just change the ROMs, you
won't need a TOS Extension Card for your STE!

As for all other XBIOS routine, registers 0-2 in both A and D are changed.
Reg A1 has the address of the routine in it, and D0,A0 have result values
(Not much in supexec I belive, except -1 if error)

I don't have my manual handy, and I give this from memory, so tell me if I'm wrong.

Patrick.

Sounds about right, standard C calling conventions. Also, you can pass in
any number of parameters (on the stack) and the called function's return
value (in D0) will be returned by Supexec. The function's argument list
will be identical to the list passed to Supexec, i.e., the first argument
will be the address of the function itself.

From my experience with high speed data acquisition equipment it is VERY
difficult (read expensive) to get even 16 bit A/D encoding without the two
least significant bits being purely noise, I would guess the same would be
true with 18bit. What the heck would the use of 24 bit processing and 20 bit
recording be when your real data is probably only 16 bits from your 18
bit A/D? Maybe they like processing and recording noise.

Sounds like the music people are falling for the placibo effect again
(remember the green pen for the edges of your CDs?).

Yes, it does indeed mean that. Some problem about the VGA monitors not
being able to handle the bandwith required for true color in that high
of a resolution. And don't quote me on that, I just know it was
some technical monitor thang that the VGA monitors were not designed for
(Oh, and they also can't do overscan, which IMHO is a big plus for
genlocking or just grabbing some extra pixels). Now, I believe that
with a multisync you _may_ be able to do better/more modes than with
just a plain VGA, but I haven't heard any details on this. When I get
my Falcon I'll try it out with Dan Aylward's PTC1426 (his TT monitor),
then I'll be able to say for sure.

Any developers/official people out there care to comment? I'm really
wondering if there is a monitor in existence which will give me all the
Falcon's cool resolutions, overscan included, without interlacing or
refusing to do high-res true color. Multisync? I hope this is the
answer, that would make it much easier to just be able to do all the
modes on one monitor, if not the VGA monitor should be sufficient, since
most people won't use 768x480 true color very often. The SC1224 is a
good option, but there's that strange interlacing problem... :-) But
it is pretty amazing what you can do with a vintage 1985 monitor, eh?
Beat a $350 VGA monitor, that's what! :)

As far as I know this is exactly what the TEC does, except that it additionally
removes the 'old' TOS completely from memory, in order to be also able to
mirror the lowest 8 Bytes to achieve a complete and instant 2.06 booting.
If you're sure you can get this to work...

|> d. jumps to that address.

Guess this should be the first in the /auto folder. I've once written a
small program to be able to boot 2.06 as RAM based version from disk. I
installed the 'old' TOS reset handler to point to the 'new' TOS one, but
had to disable the 'new' one, because otherwise you'll be in an loop
without end. Advantage: A 'warm' reset will not bring you back to your
original ROM TOS.

Er, well, don't know it, but I'll take a look for that. Maybe if you'd like it, I can send more detailed information of my patchwork. I'm not so good in the hardware specific items, I prefer the 'softer' parts.

Hasta luego,
Torsten

>"fully 32 bit computer" like Atari advertised. The only 32 bit chips in the
>falcon are the MC68030 and MC56001. All of this wouldn't make the Falcon
>all that fast and on top of this, the Falcon uses a shared bus technology
>which means if your program uses sound and number crunching and graphics
>extensivelly the performance will decrease dramatically. Not to mention
>what would happen if you dare and multitask!

You've not payd much attention lately!!! The DSP56001 have never been a
32 bit chip!! Where did you get that from; comp.sys.amiga.*???
The DSP56001 is a <quote>56bit General Purpose D.S.P.<end quote>!
It has a 24bit external databus and only 16bit addressbus.
Furthermore, several customchips in the Falcon 030 is 32 bit, and the ram
is also 32 bit. But you are right that the 68030 communicates with the
rest of the machine on a 16 bit synchronous bus!

>Now take A1200 for example.

No! I will not! I don't hav anny use for it. My TT does all i need a computer
to do. The falcon I'll phurcase to use as a sound manipulator in my stereo
system. But I'll probably also play some games on it as well!

And when the F040 comes, I'll be able to run Calamus SL faster in true color
than Calamus 1.09N in black&white on my TT.
And I don't mind the extras that comes along with the F040!

It's not only beeing an Atari fanatic that makes me do this, it's also
just darned practical to just upgrade to a new machine and go on using the
same applications. It takes a few hundred hours of using a sofisticated
application as Calamus is, to master it efficiently. I do not have time to
do this over again with a PC or MAC. (Won't even consider A's)!

Since I'm a recording engineer, I'll address this. Sure, 24- (or whatever)
-bit recording sounds better than 16-bit. 128-bit recording would probably
sound swell too. Is it necessary? Highly debateable. Can most people tell
the difference? Hardly. Is it any kind of standard? Absolutely not.

You'll find pros who like 24-bit. You'll also find a lot of VERY PROMINENT
pros who insist on analog (or at least analog for vocals/guitars). The
point is, anyone who tells you that 16-bit is automatically not professional
quality recording is full of crap.

> >>Until there are a few thousand 24-bit CD players out there (current count:

Most pros NEED no more fidelity than 16-bit digital or analog, and most pros
USE no more fidelity than 16-bit or analog.

> >Could somebody explain to me why 24-bit CD players will ever be available?

> Rounding errors in 16-bit math ARE audible as S/N degradation.

This is true, but 24-bit digital is a lot more important in sampling than in fixed-frequency recording. A lot of people won't hear those low-level problems in their original pitch, but if you sample and move the sound a couple of octaves (and maybe do some compression), this kind of thing becomes rather noticeable.

Personally, I like a little grunge on transposition, but to each his own.

> >>On the other hand, new CD players can be had for $79, so the DA conversion

Unfortunately, all we can do right now is guess. It'd be REAL helpful if some Falcon developer out there could do a S/N test on the base hardware for us.

4736. Really horrible bug in mntlib

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-05 01:31:14 UTC
From: ersmith@netcom.com
Message-ID: <1992Dec5.013114.21887@netcom.com>
Source record: 41631

There's a REALLY, REALLY awful bug in MiNT's readdir() function.
It's using the handle returned from the operating system by
opendir() as though it pointed to a block of memory. That happens
to be true in current versions of MiNT, but (a) this could
cause difficulties with some loadable file systems, and (b) the
Dreaddir() handle is likely to change in future versions of
MiNT (in fact, I just changed it in 0.97 beta and all my
MiNT aware applications blew up!)

This leads us to a big problem: if I do make the change described
to MiNT, all existing mntlib compiled programs are going to break.
Ouch. On the other hand, the programs really are broken anyway
(see (a) above) and need to be recompiled with a fixed library.

So: just how painful is it going to be to force everyone to
download new copies of MiNT utilities, shells, etc.? If we're
going to make this change, it has to be done now (before MultiTOS
is released).

Comments? Suggestions?

>Has anybody connected a PC Harddisk (no matter which model) to an Atari ST
>1040?

>Please help me to solve the never ending disk-changing-problem.

>Thanks in advance...

Sure. Other than an external case with a power supply and hopefully a fan,
you will need an ACSI to SCSI host adapter board and either a SCSI hard
disk or a harddisk controller for SCSI to MFM or RLL depending on harddisk
type. Add cables and software and that's it.

If you mean can you take one of the dirt cheap IDE drives and hook it to
your ST, I don't know of any way to do so.

More questions? E-mail me if you like.

4739. 520ST problems

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-05 05:02:27 UTC
From: at847@cleveland.Freenet.Edu
Message-ID: <1fpd53INNdg0@usenet.INS.CWRU.Edu>
Source record: 41632

When I originally picked up my 520ST (original model - no RF modulator
or internal floppy), it was DOA. When I turned it on, I got a quick flash
of gray on the sceen before it blacks out again. I threw it in the back of the
car and drove 1200 miles with it. When I pulgged it in again, it gave the
grey againaW4, then flipped to the TOS disk requester. Everything worked
fine until I tried to upgrade the memory. It constantly crashed after
turning it on. I reverted the machine back to its original configuration,
only to get my original problem back! My guess is solder balls or a loose
contact somewhere. Any better ideas?
Jeff

4740. Re: Really horrible bug in mntlib

Source record: 41635

Hmmm.... We can pay the piper now, or we can pay the piper later...
My suspicion is that now is better than later. Later, some of the
source code to utilities being written/distributed right now may
disappear from the scene. 'Twould be perhaps better for Patchlevel 25
to actually fix the bug.

Since Gcc 2.3.2 was just released this week, and may take a little
time yet to get compiled for the ST, and that's one of the largest
applications likely to break :-(, it may be a convenient time "between
compiler versions" to make the "break".

It's probably a little horrifying just how many programs are going to
break, but on the other hand, many of the developers/porters ARE on the
Net, and it might not be THAT crippling to do some recompiles...

I'd say to do it. From what you say, it's going to have to be done eventually, and all it will take to fix the programs is a simple recompile, it won't be TOO onerous. Also, if it has to be done, far better ASAP.

From the Holy Book of <1992Dec5.013114.21887@netcom.com>
as spake by ersmith@netcom.com (Eric R. Smith) :
>There's a REALLY, REALLY awful bug in MiNT's readdir() function.
[...]
>This leads us to a big problem: if I do make the change described
>to MiNT, all existing mntlib compiled programs are going to break.
>Ouch. On the other hand, the programs really are broken anyway
>(see (a) above) and need to be recompiled with a fixed library.

All programs, or just those that use readdir()? In the latter case,
what sorts of programs are we talking about? Shells and the MiNT utils,
obviously; possibly loadable file systems; compilers?; probably not
things like editors or other tools.

>So: just how painful is it going to be to force everyone to
>download new copies of MiNT utilities, shells, etc.?

Ouch... I think I'm gonna have to agree with Roger here. Saddling
ourselves with a known bug in the name of backward compatibility is not
the way to go.

> If we're
>going to make this change, it has to be done now (before MultiTOS
>is released).

Which raises a host of questions it itself, but that's another
article...

>>I work for Atari, but I don't speak for them.

Great to see you posting again Erik !

Can i be cheeky and take the opportunity to ask a question. Not related
to MiNT/MTos, but i'd bet a few quid on you knowing the answer..

The question is to do with the AES/VDI control/contrl arrays. i want to
know if their contents can be relied upon to contain the same values after
a system call (specifically the opcode). i am reliably informed that the OS
makes a private copy of them at present. i would like to use _AEScontrol[0]
as part of an error reporting routine. i can easily pass a defined opcode to
the function, but this seemed a lot more elegant. Well it works now, but will
it always ?

Adam.

4744. MultiTOS

>My opinions do not necessarily reflect those of my employer and probably are
>exact opposites. InterNet: glens@natinst.com
>---

Note that not *every* time a pixel changes color from the previous, does
the "fringing" take place. Please try to learn more about the subject you
speak instead of blasting simply because it's another computer. The 3 color
step only takes place when needing to alter all 3 guns. For example, when
going from black to white, the red gun, then the green gun, then the blue
gun, needs to be changed. When colors are close, as in digitized pictures,
where a lot of the picture is close shading of the surroundings, it takes
zero pixels to go to it's correct color. Or even in a worse case, it
usually only takes 1 pixel to get to the correct color. HAM is a way
of giving more colors without taking more memory.

btw, nice sig. "Now You're Playing With Power Without The Price!", reminds
me of a toy. I wonder why.

h>Since when does the Falcon have a 640x480x256-VGA color mode?
h>The Falcon spec-sheet does not say anything about that mode.

sorry, I know what I'm talking about - I have access to a production series Falcon, and I have the developer specs.

[digging out Falcon spec-sheet...]

Falcon030 developer documentation, October 1st 1992

XBios Vsetmode() specs:

"A few modes are not allowed ... 80 column VGA 16 bps are not supported".
32768 colors, that is. Nothing about 8 bps VGA mode.

Somewhat further down that page:

[Examples]

"For 256 color, 80 column mode on a VGA monitor:"

And, our demo Falcon030 in the store 'round the corner does have the 640x480 256col. mode available from the desktop.

so long, Peter

Source record: 41640

Just thought I'd throw my opinion in on this "REALLY horrible bug" in mntlib. Eric, _please_ do the required bug fix in MultiTOS -- if there is a problem, fix it now, even if it means we'll have to recompile all that stuff. Besides, I don't think this will affect the Falcon 030 much (most users won't be running GCC or the MiNT file utilities ten minutes after they set it up).

As for the rest of us people on c.s.a.st, I'm sure we're smart enough to handle a little recompiling and get the enw binaries distributed (right people?). :-)

So, in conclusion : a stitch in time saves nine, eh? Bite the bullet and fix it now to save us a bunch of problems later on, please.

Good luck,

Does anyone have any idea why the TEC board and AdSpeed 16Mhz accelerator
will not work on a MEGA in ANYFORM?

THanks
Mark Santora

4756. Re: VGA Monitor on 1040STf, take 2

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-06 06:49:39 UTC
From: stewart@pioneer.unm.edu
Message-ID: <v85qts_@lynx.unm.edu>
Source record: 41544

The problem with putting a VGA monitor on an Atari ST is that the Horizontal Scan frequency of the Atari at medium & low res. is around 15 kilohertz and high res is around 31 kilohertz (I believe). Standard VGA monitors won't run at 15 Khz. The way they emulate the CGA resolutions (which are around 15 kilohertz or so) is by expecting the controller card in the PC to "double scan" at 30 kilohertz which it can run at. An EGA or CGA monitor can run at 15 Khz but they are NOT SUPPOSE to be analog input. I say this becuase I expect many of them probably are because the circuitry can sometimes be cheaper. Unfortunatly these monitors won't run at high res (EGA only goes up to 21 khz). You may also have to horse around with the sync. signals because the PC monitors use combinations of inverting these signals to determine what resolutions they should run at.

Some "multi-scan" monitors may be able to work.

I am currently using a strange surplus color monitor that says: "Cotron Sword" on the front by making an adapter cable. It works but has a problem that it expects an interlaced signal so therfore there is a blank space between every horizontal line. This is okay until/unless I find a good use for my ST that was given to me in the first place!

Jim Stewart

4757. Parts info for a 16-bit sampler...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-06 08:39:45 UTC
From: jared@midiline.la.ca.us
Message-ID: <y9qcVB2w165w@midiline.la.ca.us>
Source record: 41545

What parts are required for a 16-bit 44kHz sampler, similar to the ones you plug into the cartridge port on the ST. And, if able to tell me, does anyone also know how much all the parts would cost individually?

Also I need some info on the following:

1) Where can I find a readily available 4096 color chip? What's the part number?
2) Can video RAM be addressed from regular RAM? What are the pros/cons?
3) What chips/parts are required to make use of a 2.88Mb floppy drive? I know a "AJAX" chip is needed for a 1.44Mb, but...? Is a 2.88Mb floppy at all "Motorola 680x0" compatible?
4) Where can I find an 8 voice sound chip? What other hardware/parts are required, if any. Pricing would also be helpful.
5) What amount of video RAM would be required to display 4096 colors on screen simultaneously at a resolution of 640x480?

Thanks in advance...

Might be true, but it's not documented. Perhaps Eric can help us?

Being able to pass arguments on the stack certainly would be useful,
because there are some very nasty problems with Super() in systems
with virtual memory (in short: it might happen that you set the ssp
to a swapped-out memory location, and this will result in a crash when
an interrupt occurs).

e>Comments? Suggestions?

[German developer speaking]

DO fix the bug! The nastiest things we application developers get stuck with
are old bugs left in the OS for "compatibility".
Don't worry about MiNT-aware programs already written - you clearly said that
MiNT is still beta and subject to change. They have been warned.

So please - fix every bug you find!!!!!!

Just do it - Peter

4764. Re: What devices work/don't work with the ICD Link SCSI adapter?

>
>Does anyone have a list of such devices, or general experience with the Link?-

>
>Thanks -- Volker

I had my Quantum 210 meg HD repackaged yesterday in a different case, with no
host adaptor, only two SCSI sockets. The Link plugs into one socket, providing-

a DMA socket on the back, so a normal ST hard drive cable is used to connect
the computer.

The thing seems to work perfectly OK, and I have a completely standard SCSI HD-

unit, which should be easy to re-sell, if necessary (should I ever ditch the
ST, I can put the drive on my sampler - it would only need a reformat).

Although having this lump hanging off the back of the drive is a little
inelegant, it is a cheaper and more flexible solution than the usual
arrangement. The only drawback with this setup is if you need a DMA through
socket (e.g., for an Atari laser) which is not provided.

They're not resistors, they're wire links that look like resistors. You need to find someone with some confidence and a soldering iron to change them around for you.

It's worth bearing in mind that gem 'uses' lots of the CPU time because gem
programs 'busy wait', and I have a sneaking feeling that MiNT snoops on the
common GEm entry points, and counts this time spent waiting against GEM's
process usage...

Could be wrong, of course.

4768. HPACK 0.78 binaries ?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-06 15:14:47 UTC
From: EENG6826@RyeVm.Ryerson.Ca
Message-ID: <92341.101447EENG6826@RyeVm.Ryerson.Ca>
Source record: 41515

Are the HPACK binaries available for the ST ? I've found the source on garbo.wsaua.fi (sp?) and they are over 500Kb.
This program compresses better then LZH201L by about 10% acording to my tests using the MSDOS HPACK. It also takes more time then PKZIP 1.93 but compresses better by 5-8%.
The binaries are available for most systems including: Archimedes, Amiga, MS-DOS, OS/2, Mac, Unix, VMS. I though strange that there is no Atari version. Seems the person that was doing the Atari version crashed his hard disk.

Carlos Varela.

Well, not the appropriate newsgroup, but anyway...

There exists a tiny utility named "ps2txt", which filters out at least
the plain text contained in a ps-file. Does not work with umlauts and
other strange things, but does a fairly good job. Copes also with
ps-files generated from .dvi by dvips.

Look at ftp.cs.ruu.nl:/pub/ATARI-ST/utils for ps2txt.zoo

which contains C-source and the binary.

c> falcon a "fully 32 bit computer" like Atari advertised. The only 32 bit
c> chips in the falcon are the MC68030 and MC56001. All of this wouldn't
make
c> the Falcon all that fast and on top of this, the Falcon uses a shared
bus
c> technology which means if your program uses sound and number crunching
and
c> graphics extensivelly the performance will decrease dramatically. Not
to
c> mention what would happen if you dare and multitask!

This is actually not true at all, and shows that you aren't following things
very closely at all. Not to mention the thowaway quip at the end... sheesh.

Okay : from the evidence we've heard & seen here so far - the "16-bitness"
of the falcon lies in the CPU <--> memory channel.
COMBEL, the BLiTTER, Shifter & so forth have 32-bit access to memory.

Just to colour your ignorance further - the 56001 has 24-bit external data
busses, however I think (correct me anyone) that it is 48 wide internally.

Really, if you'll stop spouting buzzwords and sit back & listen a little
more, you might eventually have something interesting to say.

Like, let's see if you can define 'a shared bus technology' in the context
of the falcon - and make it fit with all the data we've seen on how the
bird is wired. *snort*

4772. One head isn't better than two

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-06 19:40:52 UTC
From: geoffc@zebedee.uucp
Message-ID: <H.fN_jv1UbuMk@zebedee.uucp>
Source record: 41562
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

In the last few days my internal floppy disk drive had stopped working.

It just refused to read any disks at all so I took the ST appart to see if I could work out what the problem was (which I couldn't). I then tried replacing the drive with the original ST single sided disk drive (the internal drive was a double sided one I put in some time ago). The original ST drive worked OK and quite by accident I discovered that the replacement drive that I had in did work - but ONLY for single sided disks. It still refuses to read or to format double sided disks.

Any ideas as to why the drive should stop recognising double sided disks ? My guess is that there is a break in the cable going to the floppy disk drive but any other ideas would be welcome before I try replacing the cable.

Thanks

Geoffrey

4773. AMS(C++ game library): Bug fix / mailing list

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-06 22:55:05 UTC
From: warwick@cs.uq.oz.au
Message-ID: <11353@uqcspe.cs.uq.oz.au>
Source record: 41558

```
[AMS is the "Atari Machine Specific" library I've written in C++,
mainly useful for games (since non-game applications have to excuse
for being machine-specific). Interested? - email me]

Silly me, I didn't send up-to-date sources for spr.cc in AMS to account
for the improved Resolution class.

Change:
ResolutionChange FromOriginal(STLow);
to:
STLow.Use();
and change:
SourcesAcross=ScreenWidth[STLow]/SourceSpacingX;
to:
SourcesAcross=STLow.Width()/SourceSpacingX;

If you'd like to get bug reports like this in email, tell me. My list of
AMS recipients got zapped.

bgilbert@cs.washington.edu (Benjamin Gilbert) says:

>>Hmmm... does this mean I won't be able to get 640x480 true color on a VGA
>>monitor, is it only available at this resolution on an interlaced TV ??
>>Could someone please clarify this... much appreciated.
>>

>Yes, it does indeed mean that. Some problem about the VGA monitors not
>being able to handle the bandwith required for true color in that high
>of a resolution. And don't quote me on that, I just know it was
>some technical monitor thang that the VGA monitors were not designed for

VGA monitors impose no color limits. The only limit is the device driving
the monitor.

>(Oh, and they also can't do overscan, which IMHO is a big plus for
>genlocking or just grabbing some extra pixels). Now, I believe that

This is also not true.

>is released).
>

Hi all,
I think we should change the readdir() function *NOW*. It will break most
stuff, but hey, many utilities change every other MiNT version anyway,
so all we have to do is *tell* everyone in the MiNT 0.97 distribution
not to use it until they've got themselves new versions of all binaries.
It would be far worse to repair this later, as more faulty binaries would
be floating 'round the net.

One quick question to Eric: please suggest a quick fix to the library pl14;
this will allow everyone to repair this bug soonest.

Bye, Hildo Biersma

> What the hell is so new about it? It's just integrated with TOS? I can use
> MINT for my MEGA now. So what is the difference?

MINT allows you to run many TOS-programs at the same time, but you only
can use ONE GEM-program. MultiTOS has a new AES so it is possible to run
as many GEM-applications as you want.

Some "minor" advantages are these:
- Start accessories at any time
- move and resize untopped windows
- type in untopped windows
- 3D-look
- Multicolor-Icons

Still missing (in 8.1):
- Iconizing
- Drag and Drop

If you would have visited the ATARI show in Duesseldorf you would have seen
MultiTOS running at our boost :-)

:
: Comments? Suggestions?

My point of view is: Fix all bugs that you can fix _before_ MTOS
is released. While this is a more general opinion, this case
is clear: The bug may break file system drivers, so it must
be fixed anyway.

More than one GEM application at a time. Unlimited accessories.
Memory protection on the TT and the Falcon. Lots of improvements in
the AES and Desktop.

Luposian Knightwolf (jared@midiline.la.ca.us) wrote:
: 2) Can video RAM be addressed from regular RAM? What are the pros/cons?

RAM cannot access RAM. I think you actually mean "What are the
pros/cons of a split memory bus?".

Pro: Less bus contention, fast pure processing speed
Con: Limitations on the size of video RAM, some complications
im memory allocation for programmers

: 3) What chips/parts are required to make use of a 2.88Mb floppy drive? I
: know a "AJAX" chip is needed for a 1.44Mb, but...?

The Ajax is capable of driving 2.88 MB floppy drives. Just clock it
to 32 MHz and get some formatting software for this mode.

: Is a 2.88Mb floppy
: at all "Motorola 680x0" compatible?

Why not? That's about the same question as "is a VGA monitor Motorola-
compatible?" ... :)

: 5) What amount of video RAM would be required to display 4096 colors on
: screen simultaneously at a resolution of 640x480?

Depends on how you do it, by switching color palettes using raster
interrupts or using a 12 bit color map.

Referring to the rest of your questions, the cheapest and easiest
way to get what you need seems to be to buy a Falcon030.

As long as MINT and MultiTOS are still betaversions no one should complain
about changes (even if they are quite big). So I think bugs should be
corrected as soon as they are know.

One important feature of MiNT is the possibility to use different
filesystems. Don't risk anything in this area!

Well POSTSCRIPT being a Printer Description Language is normally in ASCII.
<appart from some odd ball IBM implementations which output EBCDIC and
tweak the code pages>. However I assume you want something to strip the
TEXT out. Well again the TEXT might not be there. If the original was
a TeXfile then DVI2PS produces a graphical picture of the text as
the TeX fonts are not normally available in POSTSCRIPT.

I suggest if you are really interested then you pull the GHOSTSCRIPT
sources aaand have a look at those. Dave.

4784. Sending objc_draw to a memory buffer rather than screen

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-07 17:16:06 UTC
From: hrs@aber.ac.uk
Message-ID: <1992Dec7.171606.23964@aber.ac.uk>
Source record: 41571

I'm trying to write a scrollable list box. I've gone through a number of
attempts. The best one so far was blitting n-1 of the entries in the list
and writing the nth item using objc_draw as the list is scrolled.
The trouble with this was if
the user scrolled more than one item at a time this method no longer worked
and instead the whole list box had to be redrawn (i.e using objc_draw)
at the new position - which makes for flickering and it's slow.
If the list box only moves one item at a time
the n-1 blit method works a treat and without any flicker -- the list
can also scroll pretty fast.

I'm now thinking of another method, this time to hold the entire list
(or at least the section that is being displayed) in a memory buffer
and as the list is scrolled just blit the appropriate section out to
the screen. The trouble I'm having is how do I get such a list into
a memory buffer in the first place. It's a shame that one can't redirect
the output from the objc_draw command to a memory buffer rather than
the screen (or can one?). So the question is, how can one store dialogs,
sections of object trees etc in memory (as bit maps I mean) so that they
can be blitted out to the screen at will?

I have been given binary data files that begin with, among other things,
"LHarc's SFX 1.13L (c) Yoshi, 1989".

These files seem to be self-extracting compressed archives for the IBM PC.

Running lharc (in Unix) on them gives nonsense and corrupt archive info.

Does a "LHarc's SFX 1.13L" for the Atari ST (or source code for
compilation in Unix) exist?

This may be a little much (I'm not sure of the scope of work involved here),
but would it be possible to have a patch program one may run to patch all
affected applications? If it's just a matter of replacing the library
routine, wouldn't it be possible to modify the binaries, thus everyone need
only download a single application to fix all their tools?

Naturally, for those with development systems, a relink with a corrected
library would be better, but many people don't have development systems
and downloading can be an expensive undertaking. Aim at the least common
denominator (non-developers) and remember that a lot of Atariasts are in it
'cause they're thrifty.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've got an SM124 mono monitor that is now blank 90% of the time, that is, it may boot up ok, but soon thereafter the display completely disappears as if a screensaver had kicked in. Once I just left the machine on for a while after the screen initally came up blank and it briefly came back on only to disappear after a minute or two.

I know that my screensaver is not the problem and I know I do not have a virus causing this as the problem first surfaced in Mac mode under Spectre GCR and persists even when booting with the hard drive off and no floppy in either drive. Are these the symptoms of the infamous flyback transformer problem with this monitor? Could it be the ST's circuitry and not the monitor (It's a Mega 4)? (The color circuitry does just fine on my color screen).

>_All_ programs, or just those that use readdir()? In the latter case,
>what sorts of programs are we talking about? Shells and the MiNT utils,
>obviously; possibly loadable file systems; compilers?; probably not
>things like editors or other tools.

Oops, I should have been more specific: just programs that use readdir().
That would include shells, file utilities, and emacs. It does not
include loadable file systems, which wouldn't be using the library
readdir() but would have to provide their own. Compilers are not
likely to need readdir().

(PS: I should have been more clear in my original posting: the bug
is in the MiNT library readdir(), *not* in the underlying MiNT
Dreaddir() function. That is, the kernel is fine, it's the applications
that are broken...)

I don't know whether it can be guaranteed to always work. I think it would
be much safer *not* to assume anything about the contents of the arrays
after the system call. I don't work on the AES, so I can't give a more
definitive answer than that; but if you pass the defined opcode separately
then you can be sure that your code will always work, whereas if you rely
on undocumented behaviour something may change in the future...

Eric
This is my opinion only. Atari probably has its own opinions.

4791. Re: Sending objc_draw to a memory buffer rather than screen

>the output from the objc_draw command to a memory buffer rather than
>the screen (or can one?). So the question is, how can one store dialogs,
>sections of object trees etc in memory (as bit maps I mean) so that they
>can be blitted out to the screen at will?

Sonme months ago, I posted a similar question, namely whether it
was possible to redirect the VDI output to a virtual screen of
arbitrary size and number of bitplanes. Among other hints, I was
pointed to a GDOS device driver called MEMORY.SYS, which was
supposed to become available soon that time. On another occasion,
John Henders (if I remember that correctly) told me he saw the
MEMORY.SYS driver in the FontGDOS package.
However, the MEMORY.SYS driver won't solve your problem
completely, since you still have to persuade the AES into using
the VDI handle of MEMORY.SYS, and I don't think you can do that
using any documented AES call.
Of course, you can do this the hacky way, using the XBIOS
setscreen() function to redirect the screen output to some buffer
from which you then blit according to your needs. This is
definitely not the way to go if the software you develop is
supposed to run under any multitasking TOS version, and I'm sure
the mere fact I mentioned this possibility will get me flames...
:-)
As I see it, a mix of blitting and objc_draw calls shoult work
sufficiently fast anyway.

>MiNT for my MEGA now. So what is the difference?

MultiTOS is much more than just MiNT. It includes a redesigned AES and
desktop that make it easy to run multiple GEM programs at the same time
(with just plain MiNT and the old AES you can only run 1 GEM program
at a time). Moreover, the MiNT that will come with MultiTOS has a number
of Atari enhancements (such as memory protection).

Eric
I only work for Atari, I don't speak for them.

Of course all mntlib compiled programs have to be recompiled with a fixed mntlib (because they are broken; they only used to run because they used an undocumented feature of MiNT).

However, I'd vote for a kludge that allows those broken programs to run with newer versions MiNT.

Termcap is a file that sits in the /etc directory and is a database of terminals and their capabilities. By setting the TERM environment variable you point to the particular entry in the termcap file. You can build a database entry in this file by naming it(line 1) and then entering things like the number of lines and columns the screen has and control strings for things like blanking the screen, blanking a line. Boolean switches are also used to tell whether a terminal has certain capablities, like backspacing.

My 520 ST had a similar problem. Obviously the difficulties you are encountering could be symptoms of a variety of things; some of them more serious than others. Like you suggest, the problem could be a bad solder joint somewhere. However, in my case it was just a board seating problem (quite common in the old 520ST's like yours and mine). All I did was unplug everything, grasp the computer with both hands at each end and "twist" it (as if you were holding an ice tray trying to dump out the cubes). After that, the thing came right on! This was a tip an old Atari computer repairman had told me. He said that such a treatment was VERY commonly necessary with the old 520ST's and that you made need to perform the operation occasionally to keep your computer up and running. I guess the problem has to do with a poor board layout on the inside. Hope it works for you. Let me know.

Bob

ARGGGGHHH! MTOS doesn't need any kludges! Especially in the FIRST release!

I'd bet that everything that gets broken has source freely available (since
most things that work with MiNT do), so it'll be easy to recompile bad
binaries.

From: pyr579@oz.plymouth.edu
Message-ID: <1992Dec8.022851.10693@oz.plymouth.edu>
Source record: 41587

Hello,

I just received my monitor switch box from Toad computers and
was terribly disappointed when I found that my monochrome monitor worked
very poorly from this box (which has about a 5 foot long monitor calbe
to run to the computer from the switch.) The color works. I am guessing
the problem is either signal break down or timing due to the long cable.
I'm not sure if it will be easier (anmd faster) to do a chop job on
the cable and make it about 3 feet shorter, or send it back and hope
they have a shorter version. Anyone know what the max run is? I
remember the old Monitor Master and its cable was real short, not much
over a foot. What is crazy is that a company would sell and item like
this
which obviously doesn't work.

Thanks,

Stephan

>machine on for a while after the screen initally came up blank and it
>briefly came back on only to disappear after a minute or two.

For all you people that have problems with your atari SM124 monochrome
monitors; here are some notoriusly unreliable components that you may wish to
replace. C717: this is a capacitor near the large twisted heat sink on the
right of the chassis with the back connectors facing you. This capacitor, so
near the heat sink, heats up. Once the electrolyte begins to leak the cap
deteriorats. This may end in an actual explosion (it did with mine). Simply
replace the cap with another at least 200V (I think its 4.7uF). This cap is
underated in the stock monitor and WILL go at some point.
Other caps are C716 and C715. These will cause the screen to quickly
get smaller and smaller and dimmer and dimmer (as the cap leaks). These
suffer from heat strain. There is no way to protect them except to stick
heat sinks on them.
I use my SM124 every day and have been for 7 years! These three caps
are the only things that have caused my 124 problems. There may be other
problems. Mostly it is a cap problem because of heat stress. Those 124 really
heat up and there aren't really enough heat vent on the monitor case. You can
check for a failed cap by opening up the monitor and examining the circuit
board. Look for caps that have brown goo leaking from them. These should be
replaced.

4805. FALCON BUS

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-08 08:41:56 UTC
From: bachiri@irisa.fr
Message-ID: <1992Dec8.084156.13631@irisa.fr>
Source record: 41494

How wide is really the FALCON data-bus ?
There's a controversy among the news and even here (in France)
in the different ATARI-magazine about it.
First it was said to be a 16-bit bus here, and now lots of people
affirm it should be a 32-bit bus according to the performances
compared to the TT. (It's worth noticing that the "normal" RAM in a
TT is 120 ns whereas the FALCON is at the moment (for the few ones
released) supplied with 70 ns RAM-chips.)

So is somebody sure of the fact, because (we all know ATARI I think)
they really could have choosen this (little) possibility like APPLE
made for some 68030-macintosh.

By the way, some say ATARI could being busy modifying the FALCON at
the present time. Any further informations about it ?

Better still would be to move Dreaddir() to a new function number, leaving
the old version where it is and marking the function as "reserved" with it
never being used again. This would provide backward compatability but would
stop silly people using it in the future.

I wonder if this is true. If you used the setscreen call once to
draw to and restored it immediately, is it going to be that bad, or
could it still disrupt another application. I guess if you had another
application drawing something in a topped window, and you flipped the
screen pointer, that would be bad. It makes me think that the AES should
give each application it's own screen, and handle drawing to the real
screen for them all. That would certainly be more efficient, as well, as
then ever application wouldn't have to have all the redraw and rectangle
walking code in it, the code would exist in the AES alone, and
applications would be a lot smaller.

>As I see it, a mix of blitting and objc_draw calls shoult work
>sufficiently fast anyway.

Another suggestion to speed up the lists is to make sure the text is
snapped to character boundaries. If the box the text is in is snapped,
I'm not sure that guarantees the text will be. It would probably be best
to use text objects rather than boxtext.

Please, dont make compromises, if it is necessary to change the behavior of
MiNT, make it; if it is then still possible to have those programs not break,
it would be great, but I think it is better to have a better OS than to have
old programs running. As far as I know, MiNT has been a beta version, so
changes do sometimes happen...

4809. MiNT & non MINXFS partitions problem

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-08 10:03:35 UTC
From: itschere@techfak.uni-bielefeld.de
Message-ID: <ByxqM0.1G7@hermes.hrz.uni-bielefeld.de>
Source record: 41497

Hi there!

I've had this problem before, but there's no satisfying solution so far. The story goes like this: At the moment I'm planning to install a *small* multi user system with a friend who lives next door using MiNT & Stephen Ushers init package. It's always mentioned that system security under MiNT is a joke, but there's another problem: If you don't have all of your stuff in a MINIXFS partition, everybody can access the normal partitions. So everyone who's just logged in through the RS232 line can start a gem programm, causing horrible things on the console screen. The older solution was to write a programm which makes (in my case) three dlock calls and blocks access on the non MINIXFS partitions. In this case also the console user - supposed to be allowed to execute gem programs - can't access them. Bad idea. Now how about this one:

On non MINIXFS partitions you'll get a filemode of rwxrwxrwx (rw-rw-rw-) for every file because the partition doesn't store these informations. Why not make a fix that in this case rwxrwx--- or rwx------ is reported? There are two possible problems:

1) You're not at all running a multi user system: In this case you'll never be somebody else than the super user so that you still have full access!
2) You are running such a system: In this case you'll have a MINIXFX partition installed, because otherwise it's completely nonsense. In this case you'll probably like the better access controll!

So why don't do it? Btw, has anyone the e-mail adress of the man who wrote the MINIXFS driver? I've forgotten it and cannot find it in the few docs I've not erased...

From: itschere@techfak.uni-bielefeld.de
Message-ID: <Byxqrn.1HG@hermes.hrz.uni-bielefeld.de>
Source record: 41498

hallo auch,

thinking about buying a bigger harddisk for my MegaST/E I'm wondering if the internal SCSI hostadaptor is able to handle two drives or not?! Normally it should, but I wouldn't wonder if it so cripled that it can't, exspecially because of the *strange* DIP switches on it, which are - as far as I know - used to select the target adress...

>sections of object trees etc in memory (as bit maps I mean) so that they
>can be blitted out to the screen at will?

Yes you can redirect objc_draw() output by changing the screen physical
address. Of course it won't speed anything up, in fact it'll be slower plus
you'll soak up RAM. Xcontrl list boxes scroll o.k with a decent accelerator.

Adam.

I believe that it will contain quite a lot of kludges, in the name of compatibelity to programs that used undocumented features of older versions of TOS. Even MiNT does contain a few compatibelity kludges.

> I'd bet that everything that gets broken has source freely available (since
> most things that work with MiNT do), so it'll be easy to recompile bad
> binaries.

You're perhaps right with this. However, it would still be nice if older programs that used to run under older versions of MiNT will also work under MTOS (IF it can be done; if not, or if it's too hard, it could be dropped for the sake of progress... That's why MiNT is advertised as being "beta" :-)

4814. JRI simm upgrade questions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-08 17:09:57 UTC
From: randyh@sr.hp.com
Message-ID: <ByyACM.ov@srgenprp.sr.hp.com>
Source record: 41502

Hello all,

I recently became the owner of a 520ST upgraded to 2.5 megs and TOS 1.4.
Last night I opened up the box to do the Overscan mod and discovered that
my 520ST had the JRI simm memory upgrade. I have no documentation on it
and so am hoping that someone out there can answer my questions.

I want to add another 2 megs of simms. How do I disable the 1/2 meg that's
on the motherboard? I saw one jumper on the board that plugs into the
video shifter. Do I need to remove it to add the extra ram?

Also there is an extra video shifter socket. What's the story on this?
Do I just plug in another shifter for the larger palette or do I need
some software to enable it?

Please post or email any and all information you may have about this upgrade.

Thanks, Randy Hosler

4815. EPROM PROGRAMMER FOR THE ST

Newsgroup: comp.sys.atari.st.tech

From: csi063@cch.coventry.ac.uk
Message-ID: <ByyAMr.3Hx@cck.coventry.ac.uk>
Source record: 41503

I have seen a eprom programmer circuit design for the amiga a few years back
but I don't know enough about electronics to change the bits.

The main reason behind this post is the question, has anyone designed an
eprom programmer for the ST that will handle largeish capacity roms.

If so does anybody want to mail me any details of what bits make up one
and how to put the bits together to make the programmer.

Software to drive this would also be nice ...

I hope there is someone out there who can help... Si.

True. It'll be a combined IDE host adapter with integrated TOS extension
card; as far as I know for now only for non-STE's. The driver software
is not released yet, but the hardware is compatible to AHDI 5.x (and
newer versions) anyway.

>then ever application wouldn't have to have all the redraw and rectangle
>walking code in it, the code would exist in the AES alone, and
>applications would be a lot smaller.

Ah, it's a neat idea but there remain some fundamental difficulties with this method :
1) If you have, say, 10 applications running in 640x480x16 colors (for example), you need 153KB per screen. Since the AES needs to know how to draw any part of each application's screen, it then needs to store almost 1.5MB just for screen memory! This is a ridiculous waste of space -- it's like automatically adding 153KB to the memory requested by each application. Then what about 640x480x256 on the Falcon? Now you're adding over 300KB for each application and somehow your 4MB is no longer enough. :)
2) This explains point #1 better : the AES cannot know how your program draws the graphics on its own screen. For example, your CAD program uses coordinates and vectors to represent the graphics it draws, at a _substantial_ memory savings. This way the program doesn't have to know anything about bitmaps, screen memory, etc. -- it just knows how to construct the screen from scratch using itsd own data, which may or may not already be in bitmapped format. Although it seems simple, it really is very complex for the AES to handle redraw operations for independent applications.
3) Well, this just sums up the other two... It requires a huge amount of overhead for the AES to keep track of all that graphics data in bitmapped format, while keeping track of it within the individual programs can be quite easy (your program should be able to do that anyway, even if you don't originally design it to accept redraw messages). Having the AES handle jobs which your program should do seems to violate the idea of a windowing interface. Think of what the AES would have to do to keep an updated copy of your screen -- any time any program called a routine to write to its screen, the AES would have to intercept it and send it to some other memory location, then go through all the

windows on the screen and calculate which part of each app's
window to draw. Needless to say, this would severely hamper the
performance of the system.

I hope this makes sense, I know we've discussed this topic on here before.
Are there any examples of a system which does use the environmental manager
to do screen redraws? I would think it would just complicate things
unnecessarily and would simply consume too much memory anyway.

Source record: 41512
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a SUN SPARCstation clone at home and was thinking about
dusting off the old 520 ST and somehow networking it to my SPARC.

So is there a NFS type program for the ST? We have PC's and MAC's
networked to our SPARC's here at work so I'm sure I could get a MAC
emulator and run that software, but I'd rather not. If all else
fails I could hook up a null modem connection but that is really
a jerry rig and not I'm looking for.

So any clues for me on how to do this?

Why do I want to do this? Just for the hell of it I guess.

Thanks...

4823. The internals of the MEGA ST2...

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-08 23:43:40 UTC
From: jared@midiline.la.ca.us
Message-ID: <HFmHVB1w165w@midiline.la.ca.us>
Source record: 41519

Recently, I decided to try and learn more about my MEGA ST. I picked up my BEST Electronics catalog and thumbed through it, attempting to learn what chips did what and what number they were. Little was on my side for learning. But here is my plea:

Can someone look inside their MEGA ST (TOS 1.2), assuming they have one, and list each chip number, the "term" for it (PAL, ACIA, etc.), if any, and the function of that chip? In other words, I want to know what my ST does on a parts by parts basis. There are probably a lot of similarities between the 520/1040ST and the MEGA ST, so feel free to list parts that are the same. As well, if this is of any help, my MEGA ST has 2 ROMs instead of six. Were they all made this way? And if so, why did they make such a big goof and have space for six of 'em?

Oh, and to lighten your task a bit, you needn't worry about the CPU or the Sound chip (Yamaha), the RAM, or the ROMs. I already know where they are located and what they do...

Thank you in advance.

4824. AdSCSI Micro Hostadaper trouble

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-09 05:06:04 UTC
From: mjuschke@tartarus.uwa.edu.au
Message-ID: <1g3ursINN9kp@uniwa.uwa.edu.au>
Source record: 41514

Hi,

is anybody from ICD reading this ?

I would like some answers, as I am quite unsatified with the Micro hostadapter.

I had a lot of trouble findig a SCSI drive which was low-profile, half-height
and affordable, that has a parity disable jumper.

Most suitable SCSI drives are now manufactured in permanent parity enable as it is used
with most PC's. It was only possible for me to get an affordable drive
as there were some old stock of drives availabe at one supplier. One supposedly jumpered
drive I ordered turned out with enabled parity and no jumper, as it
was already a newer model.

Can anybody give me a convincing reason why these adapters are manufactured for
no parity when the world of SCSI drives (PC's) operate with enabled parity ?

But I guess it is a tradition to make life difficult for the user. I haven't
seen a third party product that didn't cause any problems.
Be it an emulator which does not keep its promisses of peripheral speed, a TOS
extension card which sits on the processor in such a way that you cannot install
an internal harddrive to the Mega ST without having to relocate the card, even
so it could have been made to sit the other way around which would have left
plenty of space for the harddrive.

The other question is about the fact that I have been told that a high
percentage of Micro adapters are faulty out of the box.

Michael

PS. : To all third party and Atari manufacturers. Think before you build and
consider that your product is not the only thing that somebody adds to
his system.

4827. *Help* I need to make a non-standard text file standard.

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-09 06:13:28 UTC
From: mforget@elfhaven.ersys.edmonton.ab.ca
Message-ID: <H._cc6LL0jl1_@elfhaven.ersys.edmonton.ab.ca>
Source record: 41450

I really hope someone can help me out on this problem. About half way into a programmin project, I have encountered a problem that I can not seem to get around.

I normally use Personal Pascal, but in this case that is what seems to be causing the problem. I need to read a non-standard text file (the lines are seperated by 10 ($0A), which is an LF, rather than 13/10, which would be a carriage/return LF. The reason this is causing so many problems is that Personal Pascal (ReadLn) expects a perfect, standard file.

So, does anyone have C source code to read in each byte of a file, and write the data to a different file (inserting a carriage return where it should be in the new file). I have Sozobon C 1.33i so I will be able to compile programs people offer. C is not my specialty though (which you probably guessed since I have to ask for help on such a simple problem).

I tried to write a program to do this myself (in Pascal) using the fread() and fwrite() calls. This gave me an excellent copy file utility, but it would not recognize the LF. When I looked into the actual data being used, I got some very strange results. It seems as if each byte in the file buffer was representing two characters instead of one, which resulted in numeric values that did not match when compared to what I was expecting). When I wrote the file to the disk, though, it came out in good condition. I would feel better doing this in C, but I'll certainly keep trying to determine why each bytes represents two characters.

Any help would be greatly appreciated (and code would be even better).

Thanks!

The top 2 are 1 meg SIMMs, I don't know the part NO. for the Samsung ones..

Note: you must disable the 9 th bit, connect the end 3 pins together, 28/29/30 this will connect the 9 th bit inputs to VCC..

The Atari can handle as slow as 150ns, 8 or 9 bit ones...

You may look for the KA9Q port to the ST. It does SLIP, and you can use
ftp and some other TCP/IP utilities. Porting NFS for MiNT should be
possible, but I don't know that anyone has done it.

I had wondered what MEMORY.SYS did, I had a feeling that it might
be there to allow one to send VDI stuff to a memory area. I've got FontGDOS
and I can confirm that MEMORY.SYS is part of the distribution.

I guess the only way to build dialogs etc in memory is to do it by
writing one's own code. I will have to rethink the way I'm managing
the scrollable list box. Thanks though for your comments.

Does anyone have a service manual for the SM124 at all?

The local Atari distributor refuses to sell me one, despite the fact
that I'm probably more qualified to work on them than their own service
staff!
(Lots of stories of equipment coming back unfixed, or with new faults
won't be repeated here)

If someone has scanned the circuit diagrams, etc I'd be more than happy
to use them, if I can't get it on paper.

mjuschke@tartarus.uwa.edu.au (Michael Juschke) writes:

>Most suitable SCSI drives are now manufactured in permanent parity enable as it is used
with most PC's. It was only possible for me to get an affordable drive

This is definitely wrong. Most SCSI drives _DO_ have jumpers to
enable / disable parity checking.

And: don't use so long lines!

>Can anybody give me a convincing reason why these adapters are manufactured for
>no parity when the world of SCSI drives (PC's) operate with enabled parity ?

This is wrong, too. PCs are definitely not the "world of SCSI
drives".

>But I guess it is a tradition to make life difficult for the user. I haven't

This is because the ICD host adapter is simpler (and cheaper) if
it has not to deal with parity checking.

>The other question is about the fact that I have been told that a high
>percentage of Micro adapters are faulty out of the box.

I think this is wrong, too; but I can only speak for myself, and
I am running only one ICD host adapter (which perfectly meets my
needs).

Michael Juschke (mjuschke@tartarus.uwa.edu.au) wrote:
:Can anybody give me a convincing reason why these adapters are manufactured for
:no parity when the world of SCSI drives (PC's) operate with enabled parity ?

Most drives can be configured so that parity is disabled. The ACSI
bus know nothing of parity generation, so the parity information
is lost, anyway, and that's why most host adapters do not handle
parity.

: PS. : To all third party and Atari manufacturers. Think before you build and
: consider that your product is not the only thing that somebody adds to
: his system.

Most hardware kludges that third party companies come up with wouldn't
have been necessary if the ST wouldn't be that closed a system. On
the other hand, if the ST would be extensible it would also be much
more expensive ...

Well is it EVEN or ODD parity that is enabled? It does make a difference.
BTW what is suitable? Quantum, Maxtor, Seagate, Conner, and Micropolis
drives are still all selectable for EVEN, ODD, or NO parity.

> Can anybody give me a convincing reason why these adapters are manufactured for
> no parity when the world of SCSI drives (PC's) operate with enabled parity ?

PC's are not the only users of SCSI drives. Sun, HP, DEC, and Commodore are
a few of the companies that make SCSI controllers that do not require parity.
PC's have arrived relatively late to the SCSI standard, and the PC SCSI controller
cards I have seen have a jumper you can change from their standard parity to
whatever you want. Besides the SCSI spec says that parity mst be selectable.
So if what you say is true then write the PC SCSI card developers and tell
them to follow the SCSI/SCSI II standard.

> The other question is about the fact that I have been told that a high
> percentage of Micro adapters are faulty out of the box.

I own three host adapters and the only on I've replaced was the 1987 one
that does not have the correct interface drivers for the STe and TT.
They all worked right out of the box first time. Now the Micro host
adapters are only used in MegaSTs, and are not useable on the keyboard
case ST or any STe or TT, so you may be right.

XBRA is an inter-application communication protocol. It allows desk-accs and programs to talk to each other and swap data. There are several levels to the protocal, etending right up to direct swapping of .GEM/.IMG files (similar to MS Windows DDE).

I have the details (specs. and programming guides) to this protocol if anyone is REALLY interested (I posted an article on Overscan a week or so ago, after people mailed & asked me to, so perhaps this should be a follow up?).

From: bossoj@aix.rpi.edu
Message-ID: <a8c2=f@rpi.edu>
Source record: 41539

I am having a problem with my 520ST. When using various terminal programs
they seem to detect a data carrier even when the modem is not connected
to anything!! I have already tried different cables (w/ all lines
connected), setting the dips on the modem, and also using another modem!

I have narrowed the problem to the ST internals since all externals
factors have been checked out. Has anyone else had this problem or
know of a fix?? I assume that one of the controller chips is fouled.
(Please don't suggest taking it to a dealer because there isn't one around
for hundreds of miles and I it isn't abig enough problem to mail to
a dealer either!) I am capable enough with a soldering iron to fix it myself,
I just don't have any info on the ST internals!!

Thank.

Joe (bossoj@rpi.edu)

4843. Atari ST and ham Radio

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-09 18:15:45 UTC
From: camerond@cc4.crl.aecl.ca
Message-ID: <9DEC92.13154524@cc4.crl.aecl.ca>
Source record: 41536

I am considering relegating my old 1040ST with colour monitor to dedicated use in my amateur radio station, interfacing it to my radio equipment to allow me to work radioteletype, slow scan TV and packet radio, as well as receive weather satellite pictures. There are two ways, in principle, to do this. The easy (and expensive) way is to buy a sophisticated multi-mode terminal node controller that does all of the signal processing through firmware and just directs the information to the computer, that acts as a simple terminal or monitor.

The other option, which is the subject of this enquiry, is to use a relatively simple analogue/digital interface between the radio and the computer, and do all of the data processing through software in the computer. Various archives have all sorts of software to do this for the ms-dos machines (e.g. BAYCOM for packet radio), but archived ham radio programs seem relatively rare for the ST, although I have found one radioteletype program.

I would be interested in hearing from hams who have used their ST's in amateur radio employing simple interfaces, rather than TNCs. Particularly;

-what software have they used, how have they liked it and where can it be found,
-details and sources of appropriate interfaces for the various modes.

Responses to my email address please.

Don Cameron, VE3NVU

4844. TOS 2.06 Purchase

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-09 19:22:28 UTC
From: rossin@hpfcso.FC.HP.COM
Message-ID: <107480004@hpfcso.FC.HP.COM>
Source record: 41451

Anyone know where I can buy TOS 2.06? I've tried a couple of sources including Toad and D & P but they all say that Atari has back ordered the 2 chip set. Has Atari changed their mind about making it available or is this just the Christmas rush. I was hoping to work on shoving it into my ST of Christmas but now that seems grim.

Ted Rossin

Actually, MiNT maintains a private copy of the Logbase pointer for
every process, so this would be a viable approach. However, I think
there's an easier way to manage the scrollable text list - just reset
the string pointers and redraw the list.

I've got a question of my own tho (which shows my own inexperience with
GEM, sigh) - how do you update a window that is partially obscured, and
make sure that you only redraw the area that is exposed? (I'm not talking
about fielding a redraw event from AES, but when you want to draw new stuff
into a window and it is no longer the top window. Is that rectangle list
always valid, so I should just treat these two cases the same way?)

Fix it! It was always a good idea to recompile tools, shells, utilities
etc. with the newest MiNTlibs. I think we must not run into the same
trouble as Atari did by maintaining TOS bugs as "upward compatibility"
for a long time.

Regards, Markus.

4848. Re: What is TERMCAP?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-10 02:21:56 UTC
From: warwick@cs.uq.oz.au
Message-ID: <11390@uqcspe.cs.uq.oz.au>
Source record: 41448

bx074@cleveland.Freenet.Edu (Ulf Rimkus) writes:

>Recently I start to work with MiNT and GCC. Often I've found some
>words about TERMCAP and/or TERMINFO files.

TERMCAP is a very simple protocol for allowing programs to be written
that support many different TERMinal CAPabilities. Grab a /etc/termcap
file from somewhere. It consists of a list of entries of this form:

```
# Comments
#
# "\" escapes the linebreak
#
# "\E" = Escape
# "^x" = Control-x
#
# flags are just boolean yes/no values
# eg. UC means the terminal only supports lowercase.
# bs means the terminal can backspace with ^H
# HC means the terminal's cursor is hard to see (HONEST!)
#
# strings are sequences of characters
#
# eg. &8=abc means the terminal send "abc" when UNDO is pressed
# ce=\Ec means the terminal will clear to end-of-line if sent ESC-c
#
name|anothername|anothername|reallyexplicitname:\
:flag:anotherflag:value=STRING:value=#NUMBER:
```

There's a little more to it than that (such as numeric arguments to strings),
but that's the basic idea of termcap.

Further references are in other articles.

Although a lot of existing will break with that change in MiNT 0.97,
I think it's be a good idea to make that change... I don't think there
are any MiNT-specific programs out there without source, and since the
"MiNT-community" is quite active (as it seems) I guess in a couple of
weeks all important software packages will be available compiled with
the fixed MiNTlib... Besides, the GNU C compiler is being updated too
at this time, so recompiling will be a good idea. MiNT users should
get used to the idea of having the complete GNU-C package on their
harddisk! :-) Better get some memory upgrades...

|>
|> Could be wrong, of course.
|>
|> n> Juergen

I'm not sure where the busy-wait come from. Doesn't it depend on the
particular application? If the program only asks for keyboard and event
information, then all the time until this happens is available for
other GEM programs or for GEM to sit around thinking of things
(whatever a GUI operating system thinks about!).

If you mean that the GEM kernal itself busy-waits then you could be
right, but its something which could be easily remedied by Atari.
Obviously GEM will take up time, because if you think of several
processes running:

GEM Kernal \
> 1 time slice
GEM Program /

Other TOS program 1 time slice

Other TOS program 1 time slice

Obviously this depends on the priorities of the processes, but the GEM
Kernal (I hope thats the right phrase) and the GEM Program can't run
concurrently - the Kernal only runs in an evnt_multi() or AES gap, and
the GEM program only runs when its released from the evnt_multi() wait.

Oh well, thats my interpretation.

Could be wrong as well of course, so suggestions (esp from Eric!) would
be appreciated.

David.

4853. ICD Host Adapter

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-10 10:20:18 UTC
From: andrew@minster.york.ac.uk
Message-ID: <723982817.13242@minster.york.ac.uk>
Source record: 41459

I have an ICD host adapter and I'm trying to format a Quantum 105S. However, I don't have the correct configuration file for this drive, my formatting software (from ICD) only has Quantum 80S. The software is about 4 years old! Does anyone have any suggestions for formatting this drive. I keep getting Sense Code 38 at the moment.

-Andrew Hague

I think you are mixing some things here: XBRA is a standard for vector
manipulating software, so one can unchain a program from a system vector.
Many programs use it to chain themselfes into some vectors, so one can
see what programs are there and in what order.

The inter-app communication has _nothing_ to do with this, maybe you
think of the VA-protokoll?

: about fielding a redraw event from AES, but when you want to draw new stuff
: into a window and it is no longer the top window. Is that rectangle list
: always valid, so I should just treat these two cases the same way?)

The rectangle list is valid, but before (re-)drawing your window
you should call wind_update(BEG_UPDATE) to make sure that nobody
changes the rectangle list while you're drawing.

Hmmm, wouldn't it be enough to just rewrite the evnt_* routines?
Or maybe even just the evnt_multi routine because that is the one most
programs use. The only thing that needed to be added was a EVENT_PIPE
message indicating that characters are waiting in the pipeline.

Correct me if I'm wrong (I hope I am not),

Erlend.

4857. System font for GDOS?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-10 12:33:04 UTC
From: aeg03@rrz.uni-koeln.de
Message-ID: <1g7de0INN1oea@rs1.rrz.Uni-Koeln.DE>
Source record: 41457

Hi folks,

I have another foolish little GDOS question: Is it possible to
install the system font, i.e. the one that you see on a plain
vanilla ST, on GDOS devices other than the screen? Which entry is
needed in the ASSIGN.SYS file to do this?
If the ROM font are not available for installation on GDOS
printers, is it available as a GDOS font from somewhere? I
browsed through the ftp index files I currently have, but I
couldn't find it there.

Greetinx & thanx in advance, Jan

> Can't you vsync ? And what's wrong with a window ?
I don't think that he meant the sort of flicker you can get when updating the
screen as it's being displayed. I suspect the apparent flicker is caused
by clearing the redraw rect before drawing the text.

>>I'm now thinking of another method, this time to hold the entire list
>>(or at least the section that is being displayed) in a memory buffer

> Yes you can redirect objc_draw() output by changing the screen physical
>address. Of course it won't speed anything up, in fact it'll be slower plus
>you'll soak up RAM. Xcontrl list boxes scroll o.k with a decent accelerator.
NO, you should not change screen addresses, or you'll blow up with MultiTOS, or
with some graphics boards or with n other things.

To scroll the window, the method I would recommend is to blit the area that's
common to the 'before' and 'after' displays, then call your redraw routine
on the remaining rectangle at the top or bottom of the window. Blitting,
(vro_cpyfm) should normally be faster than drawing text, so only redraw the
whole window when no part is common to the 'before' and 'after' displays,
eg when the scroller has been 'paged'.

Actually, I didn't quite understand why you were drawing the text with
objc_draw; is each line in the list box a separate AES object? The approach
I use with listboxes is to make the whole of the scrollable area one object

(a G_BOX), then use VDI functions to draw the text. By mentioning 'blitting' and objc_draw, you imply that you are mixing AES and VDI calls to draw the scrollable area.

: MS Windows DDE).

You must be mixing this up with something else. XBRA is just a method
of identifying programs that re-link system vectors, nothing else.

Let us assume that we have a RAM disk driver that wants to intercept the
hdv_rw, hdv_media and hdv_bpb vectors in order to install a new
drive. This is the code to install a new hdv_rw handler:

move.l $476.w,old_rw
move.l #new_rw,$476.w
... proceed with installation ...

dc.b "XBRA"
dc.l mymagic
old_rw: dc.l 0

new_rw: ... hdv handling ...
...
move.l old_rw,-(sp)
rts ; jump to old handler

This way, a chain of handlers is installed in the hdv_rw vector.
XBRA standardizes the way the old value of the vector is stored
in your program so that an external program can follow the
complete chain and identify the programs that intercept the
vector (using the 'mymagic' ID which consists of four bytes
of ASCII).

On the ST, there are 2 pointers used with the screen. The physical and logical pointers. The physical screen is the one which is displayed on the monitor. The logical screen is where all the graphics are drawn. Normally, they both point to the same place, so that everything drawn appears on the monitor. However, you can set them to different values with XBIOS setscreen().
First, call XBIOS logbase() to find out where it currently is. Save this value, so that you can restore it later. (Never leave the log screen as being different from the phys screen when your program leaves, or the user will not see anything, not even mouse movement.)
Remove the mouse (graf_mouse() or v_hide_c())
Now call setscreen(), and just change the logical screen address to point to your buffer.
Call objc_draw(). it will "draw" the objects into the buffer.
Call setscreen again, this time passing the value you saved from logbase()
Now, you have a buffer containig the drawn object.
restore the mouse (v_show_c())
There is a way to set the width and height of the logical screen, so you may draw the whole list and then blit the part you want, but I don't have the books with me right now. Also, could someone tell me if it's a perfectly legal thing to do. It will work on any ST, and most probably on the STe, and MEGASTe. But does the TT still have this screen-switching stuff available ? Will the Falcon have it?

Patrick.

From: bpat@cs.mcgill.ca
Message-ID: <1992Dec10.175622.4703@cs.mcgill.ca>
Source record: 41466

Here's the main part for termcap. The keys are listed in alphabetical order, not by usage. (ie, arrow up "ku" is not next to arrow down "kd". There are some others in between.)
Scan through it. You'll see that there are a lot of stuff. If you want, I can post a sample termcap entry for the ST's vt52, written by Charles Savoie (chuckies@binkley.cs.mcgill.ca) and myself (Cause the vt52 in the original termcap is missing a whole lot of stuff. It can't even delete a line !!!)

>>will be identical to the list passed to Supexec, i.e., the first argument
>>will be the address of the function itself.

>Might be true, but it's not documented. Perhaps Eric can help us?

It certainly isn't documented. Under MiNT only 20 bytes of arguments
can be passed on the stack, and the called function's address is
not passed to the function, i.e.:
Supexec(foo, bar, baz)
results in a call like:
foo(bar, baz)
not
foo(foo, bar, baz).

I'll have to check and see how TOS behaves; if it does pass the function
address I'll fix MiNT, but for now it's probably best *not* to rely on
passing arguments on the stack (as far as I know this has never been
documented to work, anyway). Both MiNT and TOS will return the called
function's return value in D0, so you can rely on that.

>Being able to pass arguments on the stack certainly would be useful,
>because there are some very nasty problems with Super() in systems
>with virtual memory (in short: it might happen that you set the ssp
>to a swapped-out memory location, and this will result in a crash when
>an interrupt occurs).

Isn't that why there are separate "supervisor" and "master" stack
pointers on the 68030?

Regards,
Eric

>I'm not sure where the busy-wait come from.

GEM polls the mouse and keyboard, so it spends a lot of time "busy waiting"
for something to happen.

>If you mean that the GEM kernal itself busy-waits then you could be
>right, but its something which could be easily remedied by Atari.

"easily" is not a word I would ever use to describe changes to GEM.
Believe me, I'd like to make GEM wait nicely for events, but such
a change would require a fundamental re-working of the AES internals
(i.e. it will take a *long* time) and right now we have neither the
time nor the people to take on such a project.

Actually, the best I've seen is tarred and frozen. The Hermes
distribution comes that way, and I tried lzh'ing the directory tree
with lzh201 and it was about 10% larger. Freeze is quite slow, though.

Ian J Ray writes:
>What is XBRA?
>I have seen it mentioned in MACCEL documentation...

XBRA is a standard for how system vectors such as those used for traps
and timers can be grabbed and chained together in a sensible manner.
There are some utilities that can follow an XBRA chain displaying
the ID string for each link in the chain. XBRA is typically used with
programs that are going TSR, like MACCEL.

From: stevem@solbourne.com
Message-ID: <1g8faaINN1pr@katmandu.solbourne.com>
Source record: 41473

I know this has got to be a FAQ but here goes...

I opened my ST's box and saw that there was a whole row of
unpopulated RAM. So how do I populate this area? Is there a
procedure on-line?

If not can you tell me a few things like...

Exactly what type of memory chips do I need?

There is also an unpopulated cap (I think) next to each RAM location.
Is this just a bypass? Whats its value, .01uf?

Do I just need to solder in the right chips and caps or is there
anything else?

Thank you very much.

There *was* an Atari ST version, but as it says in the docs it was zapped when the hard drive it was on died. Unfortunately I don't have any access to an ST (it's hard enough getting to an Amiga or Archimedes to compile it :-), so I can't do it mself. If anyone would like to have a look at it, let me know - according to the person who did the ST port, it would take him about half a day to get it going again if he had a machine (your mileage will probably vary on this).

Peter.

No. XAcc is the inter-application protocol. I know it is used in
Write On and That's Write, I don't know for sure whether Compo actually
developed the protocol but I seem to remember that they did.

When I purchased Write On at the MAST Atari Fest in Milwaukee, WI,
the Compo rep told me about XAcc and later mailed me a copy of their
docs describing it.

Michel Forget writes about wanting to convert linefeed characters
to carriage return/linefeed pairs...

A very simple way to do this is to use a wordprocessor
(like ST Writer) which has Search and Replace capabilities..

I often have to do that with files from the Amiga world (for
whatever reason, their text files are formatted like this, with
just linefeeds, no CRs), and ST Writer does it just fine.

I also use the capture buffer in Flash 1.60 which has the same
capabilities to search and replace text.

ST Writer is free, and should be available from atari.archive...

As Micheal Hohmuth has kindly pointed out, I got the name of the Inter - app comms protocol WRONG. XBRA is indeed an interupt sharing convention, NOT a protocol for passing info between prgs.

BUT, all I got wrong was the name. My previous post still stands, but the name off the protocol is XACC (an easy slip, I hope you'll agree). If anyone has used WriteOn with Wallace KeyShow, this is how these programs talk to each other.

I will still be posting the details of this protocal on Monday.....

Thank you Roger for your useful comments. Of course, it's not actually Atari's standard that you're talking about - it's Microsoft's standard. That's where it came from.

Sometimes people have to translate between the Unix and MSDOS delimiters. Perhaps because they work in both environments. Perhaps because they're idiots that ought to know better. Perhaps because somene wanted to annoy people that dislike UNIX.

There's a little utility that I found at atari.archive.umich.edu called "Flip." It will "flip" the line delimiters from one to the other on demand. I recompiled it under the latest version of GCC, and may have sent a newer copy in. I don't remember. If it needs to be updated, I certainly have it around at home here, and can upload it.

Flip is happiest running under a CLI, but I have used it from the desktop. Not pretty there, but it does work.

Oh, by the way, Flip was written by Rahul Dhesi, notable as the authour of the Zoo file archiver.
Here's the output of "flip -h" on my Sun account here.

File interchange program flip version 1.00. Copyright 1989 Rahul Dhesi,

All rights reserved. Both noncommercial and commercial copying, use, and creation of derivative works are permitted in accordance with the requirements of the GNU license. This program does newline conversions.

Usage: flip -umhvtsbz file ...

One of -u, -m, or -h is required; others are optional. See user manual.

-u convert to **IX format (CR LF => LF, lone CR or LF unchanged,
trailing control Z removed, embedded control Z unchanged)
-m convert to MS-DOS format (lone LF => CR LF, lone CR unchanged)
-h give this help message
-v be verbose, print filenames as they are processed
-t touch files (don't preserve timestamps)
-s strip high bit
-b convert binary files too (else binary files are left unchanged)
-z truncate file at first control Z encountered

May be invoked as "toix" (same as "flip -u") or "toms" (same as "flip -m").

w>There is a jumper wire that must be soldered between the CPU and the
w>expansion slot connector when you install AdSpeed ST in a Mega ST.

Note: Not all Atari dealers are stupid. :-)

The jumper wire you talk about has to be inserted in Mega STs that have that strange extra chip on top of the CPU. We did that, that really is NOT the problem.

btw, without the jumper, these Mega STs wouldn't work at all, since the BGACK (bus grant acknowledge) signal wouldn't reach the CPU.

The problem with AdSpeed is, some MegaST/TEC machines don't work in a stable way; they simply crash from time to time, some have blitting problems, some will run in cold state and crash once they become warm - these are not all kinds of symptoms I've seen...

I think that would be difficult. The 1040 does not use SIMMs, so you'll need an adapter of some sort. Also note that the SIMMs from the Mac are 8 bit; they have no parity.

If you want Unix, you should not think of Atari as a hardware basis.
Atari Sys V will not be available for the F030, is - as far as I know -
still a developer's release for the TT which is horribly overpriced in
comparison with other proprietary Unix implementations.
Atari dropped further development in ASV, because they finally figured
out that "Unix is no market for Atari". ASV is said to be very stable, but
has an extremly low performance (especially when moving the mouse ;-) !
If they don't improve their device drivers and make a reasonable price,
then ASV is IMHO not at all interesting even for the expected F040.

If you want Unix, better get a 386/486 with Linux or BSD386, or simply
buy a NeXT or Sun Sparc Workstation. There are quite cheap 2nd hand
or clone computers.

Regards, Markus.

4885. Re: Sending objc_draw to a buffer

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-20 15:12:31 UTC
From: Cford@debug.cuc.ab.ca
Message-ID: <1992Dec20.151231.5801@debug.cuc.ab.ca>
Source record: 41489

Here's a suggestion:

Set the logbase() to a 32000 byte buffer. That way all drawing will be done there but the user won't see it. After each objc_draw, use BIT_BLIT to save the drawn stuff into another buffer. After you are done, set the screen back. Make sure to hide the mouse for this.

4886. XAcc protocol definition

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-21 09:45:33 UTC

```
XAcc: a communication protocol for GEM applications
===================================================

(last revision: November 28, 1992)

The XAcc protocol was originally designed for non-multitasking versions of
GEM to allow data exchange between the main application and any number of
accessories. Since the AES did not provide a function to find the
application ids (apids) of other applications without knowing their names,
XAcc had to rely on the undocumented feature that the main application
always has the apid 0. Therefore XAcc in its present form does not work in
a multitasking environment. However, AES 4.0 provides the new function
appl_search(), which allows any application to find the apids of all other
applications running concurrently. This makes it possible to design a
modified XAcc that does not use any 'dirty tricks'. This document contains
a proposal for such a modified XAcc; the changes with respect to the
previous definition are small and modifying an existing XAcc-based
application should be a matter of minutes. Since single-tasking TOS will
still be with us for a while, applications are encouraged to implement both
'traditional' and 'modern' XAcc, depending on the version number of the AES.

Purpose
-------

The GEM AES functions appl_write() and appl_read() can be used to exchange
data between GEM applications running concurrently. In practice however,
some problems need to be solved to make good use of these two functions:

- There are no standard messages for exchanging data. Their definition is
the main goal of XAcc.

- appl_write() needs the receiver's application identifier (apid). The
only way to get this (before AES 4.0) is to call appl_find(), which
needs the receiver's name. Thus communication is only possible if
the sender knows the receiver's name.
This problem is solved in AES 4.0 by the introduction of the function
appl_search().

- The main application does not know when an accessory is activated or
deactivated. This would often be useful, for example if the main
application changes system variables that could affect the accessory's
behaviour. If the main application were informed before the accessory
gains control, it could reset those to their old values and change
them back after the accessory is finished.
Another advantage would be that after an accessory has been called,
the main application could check if something has been written to the
```

clipboard or if other changes to the environment have been made.

With multitasking GEM, the situation has changed in several important ways. The possibility of using several 'main' applications in parallel makes it even more undesirable to let them directly manipulate system variables and the like; nevertheless there will probably always remain some purposes that require such methods. On the other hand, at least for applications using windows (the preferred method to get the most out of a multitasking system) it is now possible to detect changes of the active application by interpreting the new AES messages WM_ONTOP and WM_UNTOPPED. Therefore it is not considered necessary for XAcc to provide additional means to achieve this.

The communications protocol described in this document solves all these problems. It was designed for two distinct purposes:

- Exchanging data of standard types between programs that have no information about each other.

- Exchanging data between specific applications known to each other. The standard protocol ensures that program combinations from different vendors do not interfere with each other.

A potential problem caused by this protocol should be mentioned at this point: for single-tasking GEM versions, it relies on the currently undocumented fact that the main application's apid is always zero. Without this assumption there is no way to exchange data without using appl_find(). Although this fact is not documented, it holds for all single-tasking versions of GEM in existence until now, both for MS-DOS and the Atari ST (this information was confirmed by Digital Research Germany). Of course the main application's apid may be different in future versions, although there is no reason to change the current behaviour for single-tasking systems. For AES 4.0 (and later) the above assumption is not needed anyway, so no compatibility problems are to be expected in the future.

A further requirement is that all programs not using this protocol must ignore its messages. This should not be a serious problem, as all GEM applications should ignore messages they do not understand. At the time of writing no programs are known to violate this rule.

XAcc message groups

[Note: The "levels" used in previous XAcc versions have been replaced by this new concept. Compatibility issues are discussed in a special section at the end of this document.]

Both main applications and accessories can have widely different needs for communication with other programs. Therefore XAcc defines several groups of related messages that deal with a certain range of data types. The message groups always indicate the messages understood by a program, not the messages it might send to other ones. If a program supports a certain message group, it must correctly respond to all

corresponding messages, whether it can actually use the supplied data
or not.

In addition to message groups, there are the so-called "basic messages",
which must be supported by any XAcc-aware program, and program-specific
so-called "special messages".

The basic messages deal solely with identification, but no real data
exchange. They are already sufficient for programs that either do not
exchange data with others at all or use only special messages to
communicate with a number of other specific programs.

Message group 1 specifies the exchange of ASCII-format character data.

Message group 2 deals with the exchange of drawings and pictures using
the GEM metafile format and the GEM bit-image file format.

Future extensions might include sound or spreadsheet data. In addition,
a message group could be defined to handle command interchange between
applications, e.g. for a "drag&drop" protocol.

XAcc messages

There are two kinds of XAcc messages: standard messages, which must be
understood by every participating program, and special messages intended
for communications between specific program combinations. The standard
messages have numbers ranging from 0x400 to 0x7ff, special messages start
from 0x800. The latter ones may only be sent after the receiver has been
identified and is known to understand them. The following description is
only concerned with standard messages.
In addition to XAcc standard messages, the AES messages normally sent
by the screen manager may be used. The most useful ones are AC_OPEN
and MN_SELECTED; the latter one requires a knowledge of the receiver
and therefore belongs to the special messages.

Basic messages

ACC_ID = 0x400
ACC_OPEN = 0x401
ACC_CLOSE = 0x402
ACC_ACC = 0x403
ACC_EXIT = 0x404

These messages provide XAcc initialization and organization. This is
the only part of XAcc which has to be implemented in a different way for
single- and multi-tasking GEM versions. Note that the procedure
described for 'multitasking' actually only depends on the existence of
appl_search() and hence on an AES version number >= 4.0. If some
future single-tasking AES supports appl_search(), the "multitasking"
initialization should be used. Multitasking AES versions with a version
number < 4.0 should never exist; to be on the safe side, applications

should not attempt to use XAcc if such a situation is detected.

I) Single-tasking GEM versions

The communication between the main application and the accessories is initiated in the following way:

1) When a main application is started (or terminated), all accessories receive an AC_CLOSE message from the AES screen manager. In response they must send an identification to the main application according to the following format:
msgbuf[0]: ACC_ID
msgbuf[1]: sender's apid
msgbuf[2]: length of the message - 16, giving 0
msgbuf[3]: program version number and message groups
msgbuf[4] and msgbuf[5]: pointer to sender's name
msgbuf[6]: menu number (menu_id) as returned by menu_register()
msgbuf[7]: reserved (see ACC_ACC)
The low byte of msgbuf[3] contains a bitmap indicating which message groups are understood by the sender. Bit zero is set for message group 1, bit one for message group 2, and so on. This is independent of the message types which the sender might itself send to others. The sender of a message must ensure that it is understood by the receiver. The high byte is used to indicate a program version number using an arbitrary encoding scheme.
The pointer to the sender's name is stored in a machine-dependent format. The name itself is a character string following C conventions, i.e. a string of characters terminated by a zero byte. To avoid name conflicts, long names are preferred to short abbreviations. The name must be available at the given address at any time, it may not be removed after initialisation. As the version number is stored in msgbuf[3], it should not occur again in the name.
[Note: see the section "Extended names" for more details on names.]
Accessories using more than one menu entry must issue one ACC_ID message for each entry used. Accessories without a menu entry must use a number of -1.

Since msgbuf[1] and msgbuf[2] have the same meaning for all message types, they are no longer mentioned from now on.

2) In response to an ACC_ID message the main application sends an identification back to the accessory. The format is identical, except that there ist no menu number and thus msgbuf[6] can be used for any other purpose if neccessary. The same applies to msgbuf[7].

3) In addition to the ACC_ID message, the main application informs all previously registered accessories about the new one by sending them the message
msgbuf[0]: ACC_ACC
msgbuf[3]: program version number and message groups
msgbuf[4] and msgbuf[5]: pointer to accessory's name
msgbuf[6]: accessory's menu number (menu_id)

msgbuf[7]: accessory's apid

4) An accessory receiving the ACC_ACC message from the main application sends an ACC_ID message to the thereby registered accessory, identical to the one previously sent to the main application.

5) When an accessory is activated by receiving an AC_OPEN message, it sends the following message to the main application:
msgbuf[0]: ACC_OPEN
Just before the accessory returns control to another program, it sends the message
msgbuf[0]: ACC_CLOSE
When receiving ACC_OPEN, the main application restores all system variables it has changed to their original values (if possible and neccessary). After receiving ACC_CLOSE, it may set them again to any desired value.
Accessories should change system variables only after sending ACC_OPEN and restore them before ACC_CLOSE.

There have been some problems with the implementation of ACC_OPEN and ACC_CLOSE that should be mentioned. The system was designed with window-less accessories in mind, i.e. accessories that only display a dialog box. For these accessories, the above procedure is well-defined. Accessories that use windows however have no way to find out if they have been activated or deactivated, because they do not receive a message to indicate this (starting from AES 4.0, this problem is solved). Therefore such accessories must be careful with ACC_OPEN and ACC_CLOSE. The most important thing is to guarantee that ACC_OPEN and ACC_CLOSE always occur in pairs, and that in between no other program gains control. How exactly this is implemented depends on the specific application. Sometimes the best implementation is not to use ACC_OPEN and ACC_CLOSE at all.

After initialization is completed, all participating programs know the identity of all other ones, either by receiving an ACC_ID message or by receiving an ACC_ACC message. The main application is always informed about accessory activities. If in addition it proves neccessary to inform one accessory about the activation of another one, this can be accomplished by sending special messages (starting from 0x800).

II) Multitasking GEM versions

The initialization procedure is much simpler in this case. Any application, i.e. both 'standard' applications and accessories, uses appl_search() to detect all currently running AES processes when it is started. To each application or accessory (i.e. everything but system processes) it sends an ACC_ID message:
msgbuf[0]: ACC_ID
msgbuf[1]: sender's apid
msgbuf[2]: length of the message - 16, giving 0
msgbuf[3]: program version number and message groups
msgbuf[4] and msgbuf[5]: pointer to sender's name

msgbuf[6]: menu number (menu_id) as returned by menu_register()
msgbuf[7]: reserved
The low byte of msgbuf[3] contains a bitmap indicating which message groups are understood by the sender. Bit zero is set for message group 1, bit one for message group 2, and so on. This is independent of the message types which the sender might itself send to others. The sender of message must ensure that it is understood by the receiver. The high byte is used to indicate a program version number using an arbitrary encoding scheme.
The pointer to the sender's name is stored in a processor-dependent format. The name itself is a string of characters terminated by two zero byte. To avoid name conflicts, long names are preferred to short abbreviations. The name must be available at the given address at any time, it may not be removed after initialization. It must also reside in globally accessible memory. As the version number is stored in msgbuf[3], it should not occur again in the name.
[Note: see the section "Extended names" for more details on names.]
Applications using more than one menu entry must issue one ACC_ID message for each entry used. Accessories without a menu entry must use a number of -1.

When receiving an ACC_ID message, an application replies by sending a message of the same format to the original sender, the only difference being that ACC_ACC is used instead of ACC_ID. Applications with several menu entries must again send one message for each entry.

The messages ACC_OPEN and ACC_CLOSE are not used in multitasking systems.

Note: The only difference between ACC_ID and ACC_ACC for multitasking systems is that an application receiving ACC_ID sends ACC_ACC as a reply, whereas no reply is sent on receiving ACC_ACC. This prevents applications from sending ACC_ID to each other indefinitely.
Obviously the name ACC_ACC has lost its original meaning and probably should be changed. But since the symbolic names do not influence the actual behaviour of any program, this is not really important at all.

Since in a multitasking environment every participating application can terminate, some means must be provided to tell other applications about this. Therefore the message ACC_EXIT has been added to the list of level 0 messages. Before terminating, any application sends
msgbuf[0]: ACC_ID
msgbuf[1]: sender's apid
msgbuf[2]: length of the message - 16, giving 0
to all applications that have ever registered themselves by sending ACC_ID or ACC_ACC.

Extended names

Experience with XAcc has shown that it would often be useful to have more information about an application than specified with ACC_ID messages.

For example it is sometimes useful to check for a special feature that is not unique to a single program, but to several similar ones. This was the motivation for the introduction of "extended names".

An "extended name" is a character string of the format
'name'\0XDSC\0'string'\0'string'\0...'string'\0\0
i.e. a "standard" name followed by the string "XDSC" (for "eXtended DeSCription"), followed by a list of strings containing additional information. The end of the list is marked by an additional zero byte.

Each information string indicates by its first byte what kind of information it contains. Currently the following types are defined:

'1' - application type (human-readable)
The text following this byte (an ASCII-1, 0x31) should roughly specify the type of application, e.g. "word processor" or "spreadsheet". The purpose is for applications to present this information to the user to let him/her decide where data should go. This is not the place for advertising hype; a word processor should call itself "word processor" and not "document editing and design system".
It should be clear that the text should be understandable for end users, especially it should be in the language used for the user interface.

'2' - application type (machine-readable)
Currently defined are:
"WP" - word processor
"DP" - DTP
"ED" - text editor
"DB" - database
"SS" - spreadsheet
"RG" - raster graphics application
"VG" - vector graphics application
"GG" - general graphics application
"MU" - music application
"CD" - CAD
"DC" - data communication
"DT" - desktop
"PE" - programming environment

'X' - extended features
This string is used to indicate special communication capabilities of an application. It can be used to give more specific information than the message groups understood. Since this information is meant to be used by other applications rather than end users, short abbreviations are sufficient.

'N' - generic name
Often several related, but not completely identical, applications have different names. Marketing requirements may even dictate changes of the "official" brand names, making them unsuitable

for a "technical" identification. In such cases a "generic" name
for all these programs can be specified, which is mainly used
by other programs wishing to use special messages.

The "normal" name should be the "official" name of the program, just as it
is used on the package, in the manual, and in similar places. It should
be presentable to the user to let him/her decide where to send data.

Example: The address database "That's Address" identifies itself with the
extended name (in C syntax)
"That's Address\0XDSC\01database\02DB\0XMM\0XSU\0",
indicating that it is a database with features "MM" and "SU". The first
one indicates a special mail merge mode, the second one the possibility
of retrieving data by sending the key via ACC_TEXT.
(Further information on this program can be obtained from its manual.)

Message group 1

ACC_ACK = 0x500
ACC_TEXT = 0x501
ACC_KEY = 0x502

1) Transmitting text data:
msgbuf[0]: ACC_TEXT
msgbuf[4] and msgbuf[5]: pointer to text
The text may contain all printable ASCII characters (code >= 32) and the
following control codes:
0x09 TAB (may be interpreted as a space by the receiver)
0x0A LF (usually ignored by receiver)
0x0D CR (used to mark an end-of-line (or end-of paragraph)
Other control codes may only be used if the receiver is known to
understand them. The text is terminated by a zero byte.
After the text has been interpreted completely, the receiver
acknowledges by sending
msgbuf[0]: ACC_ACK
msgbuf[3]: 0 if the text was simply ignored, 1 if it was used in
some sensible way
The sender of a text message may not change the text nor send any
other text messages to the same receiver until is has received the
acknowledge.
The sender must make sure that the memory used to store the text
is globally accessible.
The receiver should normally interpret the text as if it were typed
from the keyboard. A word processor would for example insert it into
the currently edited document (this implies using CR as an end-of-
paragraph mark), a command line interpreter would interpret the text
as a command (which implies using CR as an end-of-line mark).

2) Simulation of a key press:
msgbuf[0]: ACC_KEY
msgbuf[3]: scan code of the simulated key and corresponding

ASCII code (as returned by evnt_keybd())
msgbuf[4]: state of the SHIFT keys (as returned by Kbshift())
This message should be regarded identical to a keyboard event. It can be used to send control commands to a receiver which might have been issued from the keyboard. Of course this requires a knowledge of the receiver as no standard keyboard command sets exist. It should be noted that the receiver is free to use only the ASCII code or the scan code, or both of them.
This message is acknowledged after its interpretation with
msgbuf[0]: ACC_ACK
msgbuf[3]: 0 if ACC_KEY was ignored or a given command was not understood, 1 if some action was taken.

To prevent a deadlock if a program does not properly acknowledge a message, the sender should have some way to recover. An accessory could for example stop waiting for an acknowledgement after the next AC_OPEN, a main application might time out after a sufficiently long period.

Message group 2

ACC_META = 0x503
ACC_IMG = 0x504

These message are used to exchange drawings and pictures. Only the file formats defined in the GEM documentation are used; they are sufficient to meet most requirements, and any GEM application should be able to handle them anyway.

1) Sending a metafile:
msgbuf[0]: ACC_META
msgbuf[3]: 1 for the final part, 0 otherwise
msgbuf[4] and msgbuf[5]: pointer to data
msgbuf[6] and msgbuf[7]: length of data (32 bit longword)
The metafile data is sent in the same format as they would be stored on disk. As metafiles can become quite large and especially accessories often do not have sufficient memory to store them, a file can be sent in several pieces. The receiver has to take care of assembling all parts to restore the original data, if neccessary by writing the parts to a file. The last part of a file is marked by msgbuf[3]=1. The sender may send no other data between the parts of a file. msgbuf[6] and msgbuf[7] contain the length of the part being sent, not the total length.
The receiver acknowledges each part as described for level 1.
As for text messages, the sender must make sure that the data to be transferred is stored in globally accessible memory.

2) Sending a bit image file:
msgbuf[0]: ACC_IMG
otherwise identical to 1)

Compatibility considerations

There are two major changes with respect to the original XAcc definition:

1) "Levels" have been replaced by "message groups".
The motivation for this change was that the classification according to exchangeable data types was not really a hierarchical one; there is no reason why a programm accepting graphics should also be able to understand text. The new scheme makes no such arbitrary assumptions.

There is only one situation in which a possible incompatibility could occur: an application following the "old" convention encounters a "new" application and one of them indicates 2 in the level/message group byte. This would be interpretes as "graphics only" by one and as "graphics and text" by the other. Since the number of level-2 applications was always extremely small (in fact, the author knows only of a single one), this should be no problem in practice.

2) Extended names have been introduced.
This could lead to a problem in the extremely unlikely case of an "old" application using a name string which is accidentally followed by "XDSC".

In any case it is expected that most applications will be converted to the new rules soon, if only to support MultiTOS.

Answer:

Yes, the IDE controller is builtin as standard. If I'm not wrong, it's
integrated with the blitter.

Huh? One loads the rsc with rsrc_load, gets the address of the menu with
rsrc_gaddr and then displays the menu with menu_bar -- and you claim that
it's possible that the AES uses *another* copy of the menu than the one
pointed to by the OBJECT* one gets from rsrc_gaddr??? Is this true? Wouldn't
that be _very_ strange?
Just curious... (and never having had problems with the ob_flags method).

In the last issue oc c't, a german computer magazine, they
tested some Ethrnet-boards, one of them used the PCMCIA Port
of a Laptop (or Notebook?) and it seems to be pretty fast
compared to the ISA-Slot. Well, that does *not* mean much,
but it looks like a new low-cost-standart. :-)

BTW, where will I get software to connect these Eternet-tranceiver
to my STe? I would like to build a VME to PCMCIA converter. It can't be
difficult because the PC-people have already PCMCIA ports.

4891. Re: Address space for TOS 2.06

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-21 16:11:08 UTC
From: rossin@hpfcso.FC.HP.COM
Message-ID: <107480008@hpfcso.FC.HP.COM>
Source record: 41351

I asked the same question about a month ago. Tos 2.06 starts at 0xE00000
This is very different from the location of TOS 1.00 which starts at
0xFC0000. I forget where it is exactly but I the deal is that in the days
of the 1040ST, TOS lived in a space that was 196K, TOS 2.06 needs more space
so they threw it at 0xE00000. The total byte count of the TOS 2.06 ROMs is
256K which would overlap into I/O space in the ST if placed at 0xFC0000.
In summary, I believe the following is true. I'm sure someone will yell if
I am wrong:

TOS 2.06 start: 0xE00000
TOS 2.06 end : 0xE3FFFF

This should be 256K if I can do the hex to decimal thing correctly.

Ted Rossin.

P.S. My TOS 2.06 ROMs came in and I have finished an adapter board for my
external bus of my 1040ST to map the ROMs into the above address space.
I'll give it a wirl after Christmas.

>optimized.

This has already been optimized in 1990. KAOS 1.4.1 and newer has a completely new window module that is able to minimize redraws. This TOS patch works like MAC or other GUIs that never had those mentioned problems. You get an enormous redraw speed and redraw looks much better. This mechanism is also included in the multitasking system Mag!X, the mechanism is named "smart redraw". "smart redraw" is the opposite to "TOS redraw", "TOS redraw" is also a part of MultiTOS.
What do you think about this "genious" window sizing routine in TOS that got even worse in MultiTOS?

4893. Question for Umoria (wizzard)

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-21 17:18:22 UTC
From: bert@cs.vu.nl
Message-ID: <BzMDEn.38L@cs.vu.nl>
Source record: 41341

Hello,

Sometimes the Umoria program gets locked up, the cursor is
removed and everythings locked up. I'd appreciate if someone
can solve this, but, I am already happy if someone knows how
to restart a character that gets lost when the computer is stuck.
It's really frustrating to play a fine character for say some hours
and then have to start again, not because it was killed but because
something inside the computer went wrong.

Pleas email this to :bsteeho@.cs.vu.nl

Thanks, Bert.

4894. Re: XAcc protocol definition

Newsgroup: comp.sys.atari.st.tech

From: ersmith@netcom.com
Message-ID: <1992Dec21.205804.19515@netcom.com>
Source record: 41344

The biggest problem that I see with the XACC protocol is the requirement that data be passed in pointers; that's not a nice thing under MultiTOS, since it means that memory protection must be bypassed (with some care one can restrict the memory protection bypassing to a specific memory block, but I'm afraid that many programmers won't take this care). It also makes any kind of networking difficult, although admittedly that's a less serious concern at the moment since the AES doesn't support networking.

In MultiTOS there will be a drag and drop protocol specified, using AES messages and MiNT pipes for communication.

Regards,
Eric

Source record: 41346
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I may have been the one to mention the Atari ST linux port first so let me clarify EXACTLY what I said. To my knowledge, NO ONE is working on a linux port to the Falcon. I am interesting in working on the port however. Unfortunately, I do not know enough unix guts to do it myself. I am interested in forming and participating in a team effort to do it... I am of course probably biting off way more than I can chew but 500K of my research software runs under X and the thought of being able to run it at home is too intriguing to resist...

I REPEAT NO ONE TO MY KNOWLEDGE IS WORKING ON AN ST LINUX PORT... Do you wish to work on it? Contact me by email. If there is enough interest, we can start a mailing list to decide whether this is feasible and if so, DO IT! I am incapable of doing the port myself...

I believe that such a port would bring the ST back to life despite the Katzenjammer kids... It won't make anyone a millionaire but it'll help keep it alive... As usual, Atari has given us an interesting computer, but now they are going do absolutely nothing to support it so it will survive but hardly prosper. Who cares? The PC still has $h!++y graphics and sound and it seems like it always will... So unless we're willing to sell out we're going to have to do this ourselves...

(1) Might not work with third-party graphics cards.
(2) Will definitively fail on any screen format other than the standard
ST modes.

argl And what happens if your computer has OverScan or is a Falcon
or has a 19" monitor or a graphics card of some sort or a big screen
emulation or ...

Face it: Logbase() is an XBIOS function and therefore will only
handle the standard Atari graphics modes that XBIOS knows about -
but *not* graphics modes supported by add-on graphics cards.
And that's the reason why logbase() will fail miserably on
such hardware even *if* your screen buffer has the right size.
The best solution probably is to avoid logbase() altogether.

Have you thought of a networking extension to GEM? Who do you think will draw
a menu, when the used screen is on another machine somewhere over the net?
The screenmanager there must at least have a copy of the objects to draw,
so changing simply the object's flags is not enough, you have to set up the
menu again by menu_bar, or use menu_icheck at all.
You are right when you say that your method worked for all the AES's seen
so far, but this behavior is not documented and will break when there is a
networking AES. So please reconsider your method.

Hmm, I compiled moria 5.5 under Lattice C with a few minor mods, and I don't get this problem - if the computer crashes, or I reset it, then rerun moria my original character is still there untouched. I didn't change the code to make it happen this way either, it just did. If anyone's interested in a copy I could probably upload it somewhere. OTOH, the sources are freely available, and its an easy compile, so....

They did, and Unisoft was given a Falcon. Then Atari canned the whole project
for purely political reasons (sheer incompetence, if you ask me).

Unisoft did the job, and was paid for it, and gave the finished thing to Atari.
When Atari didn't release ASV to the general public, Unisoft was so unhappy
that they even thought about distributing ASV on their own. I can guess why
they didn't do it after all :-(

>To the experts out there: just what WOULD it take to write Unix for the ST?
>Seriously...

I would say: take BSD4.4 "lite", it is supposed to have a lot of Motorola
support already, take missing things from 386bsd when possible, and write the
HW-specific things. I would love to do that, but it would take me ages. And,
I'm not sure if I should get a TT just for this.

I understand your dislike for pointers, but there are good
reasons for them:

- it is not possible to send data objects of arbitrary size using
AES messages
- it is more efficient to pass only pointers

Besides pointers are also used in other places (XBRA), so MultiTOS
will have to provide a means for pointers across processes anyway.

>since it means that memory protection must be bypassed (with some care
>one can restrict the memory protection bypassing to a specific memory
>block, but I'm afraid that many programmers won't take this care). It

I have a bit more faith in application programmers, but you might be
right. Perhaps this should be pointed out more explicitly in the
documentation. At least I can assure you that all programs currently
using this protocol allocate a buffer for the data to be passed
by Mxalloc() without allowing access to other data.

>also makes any kind of networking difficult, although admittedly that's
>a less serious concern at the moment since the AES doesn't support
>networking.

Networking would require a complete new set of AES functions, so
obviously there is no way to define data interchange protocols
now in such a way that they would work unchanges with future
networking versions.
>
>In MultiTOS there will be a drag and drop protocol specified, using
>AES messages and MiNT pipes for communication.
>
Really? It has been announced for quite some time, but so far I have
not seen anything more specific.

Anyway, this is a somewhat different problem. While drag&drop could
be implemented using XAcc, the reverse is obviously not true.
Besides XAcc was designed for standard TOS and can still be used there,
which explains why it can't use pipes and other MiNT features. With
this restriction, I see no way to avoid using pointers.

According to the "DESCRIPTIONS" file on prep.ai.mit.edu, (in /pub/gnu)

---

dld-3.2.3
Dld is a library package of C functions that performs "dynamic
link editing". Programs that use dld can add compiled object
code to or remove such code from a process anytime during its
execution. Loading modules, searching libraries, resolving
external references, and allocating storage for global and
static data structures are all performed at run time.

Dld is now available for VAX, Sun 3, SPARCstation, Sequent
Symmetry, and Atari ST machines.

Does this mean we can have dynamic libraries???? If so, where is the Atari
ST port???

In answer to myself, it's all there at prep.ai.mit.edu - the file is
dld-3.2.3.tar.Z, and it contains all the Atari stuff. How come we aren't
USING this stuff? It's COOL. If Calamus and PageStream can do nifty
external modules, so can the rest of us, with the help of DLD.

Hmmm. I would suggest using a buffer whose size is depended upon the size
of the screen. Screen are not always 32K these days espcially with the
Falcon coming up this is a bad idea!
Apart from that it's a nice idea.

Uhuh... guess I just never thought about this kind of applications et.al.
Of course y're right -- point taken :). And thanks for the explanation.

4916. TOS Versions

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-24 11:59:29 UTC
From: jvt@its.bt.co.uk
Message-ID: <1992Dec24.115929.29214@its.bt.co.uk>
Source record: 41362
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Hi,

I've just laid my hands on a second hand STe for my children to play with.
When checking it out I discovered some very strange reports. I've run
a number of programs but the first to strike me was qindex16 which
reported the TOS version as 1.2!! I checked further and found tos_vers
thought it was 1.98 with Gem 0.23 and AES 1.64. Running memmap it reported
version 1.ae(diphthong) 1/1/90.

Now my original STe is 1.6 & that reports sensibly. Any ideas what I've
laid my hands on or is it just the routines I'm running are in someway
broken. Whatever it is, it seems to run all my progs OK.

As its the holiday, could you reply to my home mail address john@its.bt.co.uk.
I should be able to read this group from home, but there's just a chance
things could go wrong (forever a pessamist).

Thanks & Season's Greetings.
John

4918. Re: Falcon BUS..

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-24 23:49:10 UTC
From: hyc@hanauma.jpl.nasa.gov
Message-ID: <1992Dec24.234910.28952@elroy.jpl.nasa.gov>
Source record: 41366
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st,comp.sys.amiga.advocacy

Well, I finally got around to compiling this with GNU C. Here are some
numbers for the Falcon in a couple different graphics modes:

Test 640x480x2 640x480x256 320x240x16

16 bit read 6206061 3413333 5610959
16 bit write 16384000 6400000 14124138
32 bit read 6301538 3442017 5688889
32 bit write 31507692 7876923 24094118

Here's a comparison from my Mega with Turbo16:

640x200x4

16 bit read 7876923
16 bit write 2884587
32 bit read 7876923
32 bit write 2884587

First, looking at the Mega-ST, the numbers clearly agree with the fact that
the ST has only a 16 bit bus. The read numbers appear exaggerated to me,
probably due to how the Turbo-16 cache works.

The numbers for the Falcon are a little less clear, but I'd figure that the
read speeds for 16 and 32 bit cases indicate a 16 bit bus, with the slightly
higher speed in the 32 bit case due to having to execute one fewer instruction
in the actual test loop. (Well, it's still the same instruction count, but does
a NOP really consume as much time as a post-increment?) The write speeds again
show the effect of caching, which makes this test a little suspect. As you
can see in the 640x480x2 case, the video doesn't slow down the processor at
all in the 16 bit write case, the write speed is the maximum achievable on
a 16 MHz processor with a 2 cycle write. Or rather, the 68030 cache is able
to make up for any delay that might be present. But for the 32 bit case,
the impact of the video becomes noticeable, being about 4% slower than the
theoretical maximum.

This test program only used a 2K data set, so the cache effects are too
significant in these results. I guess I should try it again with a 64K
data set, to override the Turbo-16's 32K cache and the 68030's on-chip
caches...

In the meantime, I'd be curious to see the results of this program run on
an Amiga, since we've been bandying around so much stuff about all this ...

Howard, what do these numbers mean? reads and writes per second?

Source record: 41371

I have an new 1.44 meg Epson drive connected to my ST as

Drive A:. It will read and write disks which have been formatted

on it fine. But I can't read the disks which it has formatted on

other drives and if I write to a disk whcich was formatted on a

different drive, it will no longer be readable.

The jumpers are set as follows:

| G | A | A | T | T | 0 | X | 1 |

| H | X | L | S | X | 2 | X | 3 |

It is jumpered as low density (720K). Is the 3 ms step rate

correct?

4924. Re: Sending objc_draw to a buffer

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-25 19:52:33 UTC
From: Cford@debug.cuc.ab.ca
Message-ID: <1992Dec25.195233.1417@debug.cuc.ab.ca>
Source record: 41376

Marinos Yannikos (nino@vmars.tuwien.ac.at) wrote:
: Cford@debug.cuc.ab.ca (Conan Ford) writes:
: : Here's a suggestion:
: :
: : Set the logbase() to a 32000 byte buffer. That way all drawing will be
: : done there but the user won't see it. After each objc_draw, use BIT_BLIT
: : to save the drawn stuff into another buffer. After you are done, set the
: : screen back. Make sure to hide the mouse for this.
: : --

: And if you want your program to be usable by other people than ST users
: without graphics cards, Overscan etc., better think about that logbase()
: and 32000 bytes buffer again...

: -MY

I should have said,"a buffer the size of the screen buffer currently
being used." Since the logbase is the place where writes are done, the
user will not see the objc_draw calls occuring provided that the
physbase() is not changed.

So this would be the procedure:

1. Hide mouse

2. Set the object tree so that the objects will originate at 0,0

3. Allocate a buffer the size needed by the screen plus 256 (the plus
256 is for old TOS versions so that you can ensure that the screen
is on a 256 byte boundary).

4. Save current logbase value and set the logbase to the beginning of the
buffer just allocated (be sure that it is on a 256 byte boundary).

5. Create x buffers of y size, where y is the size of the memory needed
by each "page" when saved with BITBLT, and x is the number of
"pages".

6. Use objc_draw to draw each "page", and then use BITBLT to save it.

7. Restore logbase() to old value.

8. Deallocate the buffer which you are using for logbase().

9. Show mouse.

10.If that doesn't work with all screens I don't know what will.

N.B> It's not a good idea to use MALLOC seperately for each "page". If
you're using C or Basic, you should be able to use arrays, and if
you're using assembly language you will have to allocate them as
one and set up some pointers to each "page". This is because of
the problems GEMDOS has when you use MALLOC for more than 20
seperate buffers (e.g. system crash :-)).
(Though you probably know :-))

You must contact Atari Corp. itself for ASV, it is still a developer's
release - correct my if I'm wrong.

If you want to hear my personal opinion about ASV: Forget about it and
buy a 486 with Linux for less money (I do!).

Regards, Markus.

Let's just hope this BUG has been fixed in MiNT. There it would REALLY be
annoying. It's annoying now, you have to allocate memory and manage it
yourself but of course TOS should do that for you.
BTW, is that 20 blocks per program or totally?

>reported the TOS version as 1.2!!
>
>Now my original STe is 1.6 & that reports sensibly.

Quick Index has a really brain dead bug in it in the way it reports the
TOS version. Quick ST 2 did the same thing, although Quick ST 3 was fixed
to correctly display "1.62".

The bug is that Quick Index reads the TOS version word from the ROMs, which is
a hex number in the form $0XYY, where X is 1 or 2 and YY is 00, 02, 04, etc.
TOS 2.06 has a version word of $0206, TOS 1.4 is $0104, TOS 1.6 is $0106, etc.

When some horrible bugs in TOS 1.6 were found, Atari released an updated TOS 1.6
which they called TOS 1.62, and gave it a version word of $0162. The way
Quick Index and Quick ST 2 were written, they ignored the third digit and so
only printed "1.2" as the version number. That's the bug.

TOS 1.6 is really TOS 1.06, TOS 1.4 is really TOS 1.04, etc, but people didn't
seem to start using this numbering convetion until TOS 2.06. You notice that
nobody refers to TOS 2.06 as "TOS 2.6", whereas everybody refered to TOS 1.06
as "TOS 1.6". When Quick Index was being written, it was with the assumption
that the third digit of that word in ROM would always be a 0. Dumb assumption.

OK, SO I MADE A STUPID MISTAKE! YES, ____ME____!!!!!! GO AHEAD, FLAME ME!

F L A M E M E !!!!!!!!!!! <grin>

Unfortunately this bug will never be fixed since I lost the source code to
Quick Index about two years ago and don't care to rewrite it. Yes, I had it
on a hard disk and didn't bother to back it up for about 6 months. Then one
day I was booting my ST and didn't realize that the hard disk cable has partly
loose, which for whatever reason caused my SH204 drive to start formatting
itself! So the last source code I have is for Quick Index 2.0 I think which
doesn't have benchmarks for the TT. :-(

OK, SO I MADE ANOTHER STUPID MISTAKE! F L A M E M E !!!!!!!!!!!

4934. file transfers

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-28 21:08:48 UTC
From: wayne@bragg.bio.purdue.edu
Message-ID: <BzzMqp.64u@mentor.cc.purdue.edu>
Source record: 41386

Hello to all,
Our lab needs to transfer files from Atari ST
(STe) machines to Mac II ci. The files are large and
are on 44MB syquest drives (250 -300 MB worth of info),
so using DOS formatted 720 K floppies is NOT AN OPTION.
We can take care of converting the data files to a format
usable on the Mac, the $64 question is how to port the data
from the Atari to the Mac.
So far we see two options.
1) Direct serial transfer via a lan or a null modem on the
Atari and the serial port on the Mac. For this we need and
information on modems and where to get terminal SW for the
Atari (preferably PD).

2) Create a DOS partition on the Syquest (any hints?) and
writing the data to that partition. The data could then be
retrieved by a Mac using Raccess PCS once a Syquest is
converted over to use for the Mac. The question here is,
can TOS recognize the Syquest partition and write to it?

If anyone out there has any ideas, information
(or better yet) practical experience with this sort of an
operation please E-MAIL me (wayne@bilbo.bio.purdue.edu).

Thanks in advance
Wayne

Hi!

I think I might be having a problem with my hard drive. It used to only happen when it was cold in the room where the hard drive is, but now it seems to happen every time I turn the drive on.

The problem itself is this; after a few minutes of operating normally, it suddenly gets louder and sounds like it is working harder/going into Warp. It usually stops (then again sometimes it doesn't) if I tilt the front of the hard drive up.

The hard drive is an Atari MegaFile 30, by the way.

Do I need to clean the inside of the drive, or is it something else? Should I worry about this? The difference in sound is very noticeable (and there is a slight hissing as well).

Please help!

greetings to the world...

i'm a bit confused now, if the falcon will/is come out/coming out with an external SCSI or SCSI/2 port. i think i'll not buy the '030 but wait another year for a machine which is a bit more up to date... but i'm having lots of problems with free space on my MSTE/4's internal harddisk _now_ and i'd like to buy a much bigger one (it's SCSI) _now_, but use it on the falcon 040 or whatever its name will be later. now has it got a SCSI port or a SCSI/2 port? or is it possible to software-configurate SCSI/2 ports to drive the older 8 bit units?

couldn't be so difficult to answer, but i don't know...
any help would be appreciated...

A third option is to use MacSee sold by Compu-Seller West (Don Bahr,
proprietor) (220 1/2 West Main Street; St. Charles, Il. 60174)
(708) 513-5220. It will do just the trick allowing one to read or
write MacIntosh volumes (HFS or MFS) with your Atari ST or TT.

Atari Explorer On-Line Issue 12 (8/29/92) had a review claiming it
worked flawlessly during testing and was as fast as ST/TT floppy
or harddisk copies respectively. GEM interface, no fuss, no mess,
no strain. It also mentioned it works great with Syquests.

Happy computing, Wayne Booth
(only a Happy customer of Compu-Seller West and always interested
in supporting our local dealers.)

From: jrt@hardy.u.washington.edu
Message-ID: <1hq76sINN49f@shelley.u.washington.edu>
Source record: 41391

I foolishly downloaded fools.lzh (this may not be exact spelling of filename) from atari.archive.umich.edu . I then tryed to unarchive the file, but had no success after tring different utilities, unlzh172.prg, arc_lzh.ttp, lzh201le.ttp, and lzh201k.ttp. Then I tried to delete the folder that contained the garbled files from the aborted unarching, but to my chagrin discovered that I was unable to delete it! The file names are all shadowed, and contain control characters.

I would appreciate any suggestions on how to get rid of the offending folder, which is on Drive C---short of zeroing the entire partition. I am using TOS 1.0

Thank you in advance,

Jerry Thompson

4942. QUESTION: Syquest 44 boot

The start-up program is saved in the DESKTOP.INF file. Try using something like Desk Manager to pick which DESKTOP.INF to boot up with.

E-mail bounced.

For option #2, would this help (from the latest ICDBOOT read.me)?

- ICDBOOT now recognizes hard disks formatted and partitioned
with MS-DOS and FDISK on a PC. This should simplify the
transfer of files between PCs and STs using removable media
(SyQuest, etc.) much easier. NOTE: (a) although reading and
writing MS-DOS partitions is supported, most of the ICD
utilities will not work with MS-DOS partitions. (b) very large
DOS partitions have too many data clusters, which confuses TOS,
so some DOS partitions will not be entered into the drive
tables and will not be useable.

4945. Sozobon C for the mac?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-30 17:54:44 UTC
From: brad@tazboy.jpl.nasa.gov
Message-ID: <BRAD.92Dec30095444@tazboy.jpl.nasa.gov>
Source record: 41396

The following was a follow up to a message that was cross posted to
comp.sys.atari.st.tech and comp.sys.mac.programmer concerning the
posibility of porting Sozobon C to the mac. I wanted to see if
this would generate some interest from some atari people.

basically I would really like too hear from people who know a bit
about TOS, MiNT, and/or Sozobon C, and who wouldn't mind getting
questions from a mac person.

Thanks,
Brad Pickering (brad@tazboy.jpl.nasa.gov)

Newsgroups: comp.sys.mac.programmer
From: brad@tazboy.jpl.nasa.gov (Brad Pickering)
Subject: Re: Sozobon C - a free C for the Mac, too?
In-Reply-To: ngse18@castle.ed.ac.uk's message of 29 Dec 92 16:32:46 GMT
Followup-To: comp.sys.mac.programmer
Nntp-Posting-Host: tazboy.jpl.nasa.gov
Organization: Jet Propulsion Laboratory, Pasadena, CA
Distribution: comp
Date: Tue, 29 Dec 1992 19:27:39 GMT

I think this is a great idea. In fact, this is sort of what I have been
playing with for the past couple of weeks. What I want to do is emulate
TOS (the atari OS) on the mac so that all of the atari tools can work
on the mac with no changes. I started with the source to MiNT and
compiled it under Think C tweeking it quite a bit so that it wouldn't
trample the mac os. So far I have been able to run some very simple
programs like 'echo' and 'cp'. I still have lots of problems with
more complicated programs like 'sh'. I am especially having difficulty
with the fork calls. It has something to do with the code I modified
so that all processes would run in supervisor mode. Any way, I just
ordered a book on the 68040 so that I could investigate running user
level code on my mac.

Assuming we got something like this running, we could use the same sort
of techniques that MacMINIX uses to write mac code useing a regular
K&R compiler. In mac minix, mac traps are interfaced by code that loads
the appropriate a5 from a global variable before calling the trap.
Instead of pc relative code generation like most mac compilers, atari
compilers generate relocation information so that it can be relocated
at execution time. On the mac, we could have the first routine be
a pc relative routine that loads and relocates the TOS formatted exectable
from a resource. One of the biggest problems with this is in debugging.
Macsbug expects the names of routines to be imbedded into the code at

the end of each routine. Sozobon C doesn't put this information in the code, so bugs are much more difficult to track down.

My opinion is that the goal of getting Sozobon C generating Mac Programs is very doable. I am very curious about what the atari people think about this. Are there any atari people out there who know a bit about TOS, MiNT, and/or Sozobon C who wouldn't mind a few questions from some mac people.

Anyway, theres my comments. I would certainly like to see this discussion continue.

Brad Pickering

SCSI-2 is fully compatible with SCSI-1. The only problem you will have is getting a cable with the SCSI-2 connector on it. I've got my Quantum and Syquest hooked up to the Falcon now with no troubles. (Except that it didn't like it when the Mega-4/ICD was also on the bus; I had to pull them off...)

4949. How do you set a disk's volume label?

Newsgroup: comp.sys.atari.st.tech
Date: 1992-12-31 17:24:26 UTC
From: rdo@kynes.bison.mb.ca
Message-ID: <H.ea.kYwLB_Rm3xg@kynes.bison.mb.ca>
Source record: 41403

Using the following code, I can find the volume label on a disk:

```
#include <stdio.h>
#include <string.h>
#include <osbind.h>
#include <ostruct.h>

/* Get disk vol for specified drive */
char *
getvol(char drive)
{
_DTA *dta;
char path[8];
char *vol = NULL;

path[0] = '/';
path[1] = drive;
path[2] = '\0';
chdir(path);
Fsfirst("*.*", FA_LABEL);
do {
dta = (_DTA *)Fgetdta();
printf("name: %s\n", dta->dta_name);
if (dta->dta_attribute == FA_LABEL) {
vol = strdup(dta->dta_name);
break;
}
} while (Fsnext() == 0);

if (vol != NULL)
return vol;
else
return NULL;
}
```

Now, what I'd like to do is be able to change an existing label. Or, if one doesn't exist, I'd like to create it.

Any ideas?

```

Well I can't say specifically what is wrong but having talk to service techs
about Atari drives I recall that the MegaFile 30 was not a very reliable drive
and invariably died in about a year. He recommended to stay away from this
drive and get a MegaFile 20 or 60 as they had much more reliable workings (I've
had my 20 for many years). I realise that this doesn't help you much. I would
suggest backing it up immediatly and having it looked at.

Bob
